ELSEVIER

Contents

UNIT I

Health and Health Care in Canada

- 1 Health and Wellness, p. 1
- 2 The Canadian Health Care Delivery System, p. 15
- 3 The Development of Nursing in Canada, p. 29
- 4 Community Health Nursing Practice, p. 42

UNIT II

Foundations of Nursing Practice

- 5 Theoretical Foundations of Nursing Practice, p. 54
- 6 Research as a Basis for Practice, p. 65
- 7 Nursing Values and Ethics, p. 80
- 8 Legal Implications in Nursing Practice, p. 94
- 9 Global Health, Culture, and Diversity, p. 107
- 10 Nursing Leadership, Management, and Collaborative Practice, p. 125

UNIT III

Approaches to Nursing Care

- 11 Critical Thinking in Nursing Practice, p. 140
- 12 Nursing Assessment and Diagnosis, p. 153

ing and Implementing Nursing Care,

tion of Nursing Care, p. 193

15 Documenting and Reporting, p. 202

16 Nursing Informatics and Canadian Nursing Practice, p. 228

UNIT IV

Working With Patients and Families

- 17 Communication, p. 242
- 18 Caring in Nursing Practice, p. 262
- 19 Family Nursing, p. 273
- 20 Patient Education, p. 290

UNIT V

Caring Throughout the Lifespan

- 21 Developmental Theories, p. 309
- 22 Conception Through Adolescence, p. 326
- 23 Young to Middle Adulthood, p. 361
- 24 Older Adulthood, p. 374

UNIT VI

Psychosocial Considerations

- 25 Self-Concept, p. 396
- 26 Sexuality, p. 415
- 27 Spiritual Health, p. 433
- 28 The Experience of Loss, Death, and Grief, p. 447
- 29 Stress and Adaptation, p. 472

UNIT VII**Scientific Basis for Nursing Practice**

- 30 Vital Signs, p. 489
- 31 Health Assessment and Physical Examination, p. 537
- 32 Infection Control, p. 618
- 33 Medication Administration, p. 662
- 34 Complementary and Alternative Therapies, p. 751

UNIT VIII**Basic Physiological Needs**

- 35 Activity and Exercise, p. 769
- 36 Safety, p. 790
- 37 Hygiene, p. 825
- 38 Cardiopulmonary Functioning and Oxygenation, p. 877
- 39 Fluid, Electrolyte, and Acid-Base Balances, p. 936
- 40 Sleep, p. 992
- 41 Pain Assessment and Management, p. 1017
- 42 Nutrition, p. 1050
- 43 Urinary Elimination, p. 1112
- 44 Bowel Elimination, p. 1159

UNIT IX**Patients With Special Needs**

- 45 Mobility and Immobility, p. 1195
- 46 Skin Integrity and Wound Care, p. 1250
- 47 Sensory Alterations, p. 1301
- 48 Care of Surgical Patients, p. 1325

Appendix A: Practical Nursing in Canada,
p. 1371

Appendix B: Laboratory Values, p. 1388

References, p. 1400

Review Question Rationales, p. 1455

Index, p. 1475

Special Features

PATIENT (CLIENT) TEACHING

- Box 20-9 Teaching Strategies, p. 301
- Box 23-5 Encouraging Positive Health Habits, p. 371
- Box 25-11 Alterations in Self-Concept, p. 412
- Box 28-9 Preparing the Dying Patient's Family, p. 466
- Box 29-9 Stress Management Strategies, p. 484
- Box 31-6 Skin Assessment, p. 550
- Box 31-10 Hair and Scalp Assessment, p. 557
- Box 31-12 Nail Assessment, p. 559
- Box 31-14 Eye Assessment, p. 563
- Box 31-15 Ear Assessment, p. 564
- Box 31-16 Nose and Sinus Assessment, p. 568
- Box 31-17 Mouth and Pharyngeal Assessment, p. 569
- Box 31-18 Neck Assessment, p. 572
- Box 31-19 Lung Assessment, p. 579
- Box 31-20 Heart Assessment, p. 582
- Box 31-21 Vascular Assessment, p. 586
- Box 31-24 Female Breast Assessment, p. 593
- Box 31-25 Abdominal Assessment, p. 596
- Box 31-26 Female Genitalia and Reproductive Tract Assessment, p. 600
- Box 31-27 Male Genitalia Assessment, p. 600
- Box 31-29 Rectal and Anal Assessment, p. 604
- Box 31-30 Musculoskeletal Assessment, p. 606
- Box 31-33 Neurological Assessment, p. 614
- Box 32-17 Infection Control, p. 647
- Box 33-11 Safe Insulin Administration, p. 687
- Box 34-5 Relaxation, p. 758
- Box 34-7 Creative Visualization, p. 760
- Box 36-10 Correct Use of a Fire Extinguisher in the Home, p. 808
- Box 36-14 Prevention of Electrical Hazards in the Home, p. 820
- Box 37-14 Contact Lens Care, p. 864
- Box 38-12 Cardiovascular Disease, p. 900
- Box 39-9 Primary Health Care and Patient Teaching: Preventing and Managing Chronic Kidney Disease, p. 958
- Box 39-13 Home Intravenous Therapy, p. 989
- Box 42-9 Food Safety, p. 1079
- Box 43-13 Pelvic Floor Muscle Exercises (Kegels), p. 1155
- Box 45-2 Patients With Osteoporosis, p. 1200
- Box 45-11 Crutch Safety, p. 1244
- Box 46-11 Pressure-Redistribution Surfaces, p. 1276
- Box 48-6 Postoperative Instructions for Ambulatory Surgical Patients, p. 1360

CONCEPT MAPS

- Figure 12-4 Ms. Devine's Nursing Assessment Findings, 162
- Figure 12-9 Ms. Devine's Nursing Diagnoses, p. 169
- Figure 13-4 Planning Ms. Devine's Nursing Care, p. 184
- Figure 13-6 Planning Ms. Devine's Postoperative Nursing Care, p. 188
- Figure 25-7 Client After Surgical Reconstruction of Severe Facial Scars, p. 410
- Figure 26-5 Patient With Decreased Libido and Depression, p. 429
- Figure 28-4 Patient With Depression After the Death of his Wife, p. 461
- Figure 29-6 Patient With PTSD After Experiencing a Severe Physical Assault Four Months Ago, p. 483
- Figure 35-7 Patient With Heart Failure and Decreased Activity, p. 781
- Figure 36-5 Patient With a Cerebrovascular Accident Three Months Previously With Left-Sided Paralysis, Two Days After Right Femoral-Popliteal Bypass, p. 802
- Figure 37-7 Patient With Alzheimer's Disease and Hygiene Needs, p. 839
- Figure 38-8 Patient With Chronic Obstructive Pulmonary Disease and Pneumonia, p. 899
- Figure 39-10 Patient With Gastroenteritis and Dehydration, p. 957
- Figure 40-5 Patient Who Has Depression Following the News of her Mother's Recent Cancer Diagnosis, p. 1009
- Figure 41-9 Patient With Pain Related to Rheumatoid Arthritis, p. 1035

RESEARCH HIGHLIGHTS

- Figure 42-7 Patient With Myasthenia Gravis, p. 1077
- Figure 43-13 Patient With Urinary Tract Infection (UTI) and Dementia, p. 1133
- Figure 44-10 Patient Who Has Ovarian Cancer With Bone Metastases and Constipation, p. 1173
- Figure 45-11 Patient With Quadriplegia Related to an Acute Spinal Cord Injury at C7, p. 1216
- Figure 46-22 Patient With a Chronic Wound, p. 1273
- Figure 47-3 Patient With Retinal Detachment of Right Eye After Blunt Injury to Forehead, p. 1312
- Box 4-5 AIDS Prevention Street Nurse Program, p. 49
- Box 6-5 Renewing Everyday Hope: The Hope Experience of Family Caregivers of Persons With Dementia, p. 76
- Box 7-6 Ethics in Nursing Practice, p. 91
- Box 9-3 Globalization and the Cultural Safety of an Immigrant Muslim Community, p. 113
- Box 9-7 Intergenerational Trauma: Convergence of Multiple Processes Among First Nations Peoples in Canada, p. 121
- Box 9-8 Contemporary Perceptions of Health From an Indigenous (Plains Cree) Perspective, p. 122
- Box 11-2 Working Relationships of Public Health Nurses and High-Priority Families, p. 146
- Box 11-4 Decision Making by Baccalaureate Nursing Students, p. 149
- Box 14-1 Nursing-Sensitive Outcomes, p. 196
- Box 16-2 Evaluating Standardized Nursing Terminology, p. 236
- Box 19-7 Research Focus: Therapeutic Conversations With Family Members Experiencing Childhood Cancer, p. 283
- Box 20-3 The Effectiveness of Nurse-Directed Patient Education, p. 292
- Box 21-3 Toxic Stress and Development, p. 320
- Box 21-5 Supporting Parents: Can Intervention Improve Parent-Child Relationships?, p. 324
- Box 22-5 Breastfeeding, p. 337
- Box 23-3 Peer Navigators: Social Support During Health Challenges, p. 364
- Box 24-9 Designing a Fall-Prevention Strategy That Works, p. 393
- Box 25-3 Adolescent Self-Concept and Health, p. 402
- Box 25-4 Bullying and Self-Concept, p. 404
- Box 25-6 Promoting a Healthy Body Image, p. 405
- Box 26-1 Gender Issues and Sexual Desire: The Role of Emotional and Relationship Issues, p. 418
- Box 27-4 Mapping the Process and Qualities of Spiritual Nursing Care, p. 437
- Box 28-5 Family Perception of End-of-Life Care, p. 457
- Box 29-2 Understanding Risks for Developing Psychological Distress, p. 476
- Box 29-3 Spousal Support for Psychological Distress, p. 478
- Box 32-11 Reducing Surgical Site Infections, p. 639
- Box 32-14 Adverse Effects of Isolation, p. 643
- Box 34-3 Tai Chi as an Intervention to Improve Balance and Reduce Falls in Older Adults, p. 756
- Box 35-17 Energy Requirements of Tai Chi, p. 787
- Box 36-11 Effects of Nursing Rounds, p. 810
- Box 38-13 Ethnic and Gender Differences in Patient Education About Heart Disease Risk and Prevention, p. 900
- Box 39-10 Using Phlebitis and Infiltration Scales for Assessing PVAD, p. 970
- Box 39-14 Managing Chronic Kidney Disease, p. 989
- Box 40-3 Sleep Duration and Obesity, p. 996
- Box 41-7 Sucrose for Reducing Pain in Infants, p. 1028
- Box 42-14 Accuracy in Determining Placement of Feeding Tubes, p. 1101
- Box 43-12 Promoting Conservative Therapies for Older Adults, p. 1154
- Box 44-6 Constipation in Older Adults During an Acute Hospital Stay, p. 1174
- Box 45-4 The Meaning of Mobility, p. 1212
- Box 47-5 An Assistive Device May Be Viewed as a Stigma of Dependency, p. 1310

- Box 47-10 Self-Reported Sensory Impairment and Life Satisfaction in Older French-Speaking Adults, p. 1316
- Box 48-1 Pain Management Following Discharge After Ambulatory Same-Day Surgery, p. 1335

- Box 13-4 Acute Pain, p. 183
- Box 20-8 Learning Needs, p. 300
- Box 25-9 Disturbed Body Image, p. 408
- Box 26-4 Sexual Dysfunction, p. 428
- Box 28-8 Ineffective Coping, p. 459
- Box 29-7 Caregiver Role Strain, p. 482
- Box 30-9 Hyperthermia, p. 504
- Box 32-2 Perils of Central Venous Catheters, p. 625
- Box 32-7 Risk for Infection, p. 630
- Box 35-10 Activity Intolerance, p. 782
- Box 36-5 Risk for Injury, p. 800
- Box 37-6 Self-Care Deficit: Hygiene (Foot Care) Related to Visual Impairment and Knowledge Deficit, p. 839
- Box 38-11 Ineffective Airway Clearance/Retained Secretions, p. 898
- Box 39-8 Fluid Volume Deficit, p. 956
- Box 40-12 Disturbed Sleep Pattern, p. 1007
- Box 41-11 Acute Pain, p. 1034
- Box 42-6 Imbalanced Nutrition: Less Than Body Requirements, p. 1075
- Box 43-4 Mixed Urinary Incontinence, p. 1131
- Box 44-8 Constipation, p. 1177
- Box 45-6 Impaired Physical Mobility, p. 1214
- Box 47-7 Disturbed Sensory Perception, p. 1313
- Box 48-4 Deficient Knowledge Regarding Preoperative and Postoperative Care Requirements, p. 1339

- Box 27-5 Understanding a Patient's Spirituality, p. 439
- Box 28-10 Care of the Body After Death, p. 468
- Box 30-5 Measurement of Temporal Artery Temperature, p. 501
- Box 30-6 Use of a Glass Thermometer, p. 502
- Box 30-15 Palpating the Systolic Blood Pressure, p. 530
- Box 30-16 Electronic Blood Pressure Measurement, p. 532
- Box 32-13 Caring for a Patient on Isolation Precautions, p. 641
- Box 32-15 Donning a Surgical-Type Mask, p. 645
- Box 33-16 Giving Medications Through a Nasogastric Tube, Intestinal Tube, Gastrostomy Tube, or Small-Bore Feeding Tube, p. 698
- Box 33-17 Administering Nasal Instillations, p. 699
- Box 33-18 Administering Ear Medications, p. 704
- Box 33-19 Administering Vaginal Medications, p. 705
- Box 33-20 Administering Rectal Suppositories, p. 707
- Box 33-23 Mixing Two Kinds of Insulin in One Syringe, p. 721
- Box 33-26 Subcutaneous Butterfly Catheters and Hypodermoclysis, p. 748
- Box 36-7 Interventions for Accidental Poisoning, p. 805
- Box 37-12 Care of Dentures, p. 860
- Box 37-13 Shampooing the Hair of a Bed-Bound Patient, p. 862
- Box 37-16 Making an Unoccupied Bed, p. 874
- Box 41-13 Massage, p. 1038
- Box 42-13 Discontinuing Enteral Feedings via Nasogastric Tube, p. 1100
- Box 42-15 Obtaining Gastrointestinal Aspirate for pH Measurement, Large- and Small-Bore Feeding Tubes: Intermittent and Continuous Feeding, p. 1101
- Box 42-17 Providing Suction, p. 1104
- Box 43-11 Condom Catheter, p. 1153
- Box 44-1 Measuring Fecal Occult Blood, p. 1170
- Box 44-10 Digital Removal of Stool, p. 1185
- Box 45-7 Application of Sequential Compression Stockings, p. 1218
- Box 45-8 Application of Elastic Stockings, p. 1219

SKILLS

- Skill 30-1 Measuring Body Temperature, p. 495
- Skill 30-2 Assessing the Radial and Apical Pulses, p. 507
- Skill 30-3 Assessing Respirations, p. 515
- Skill 30-4 Measuring Oxygen Saturation (Pulse Oximetry), p. 518
- Skill 30-5 Measuring Blood Pressure, p. 524
- Skill 32-1 Handwashing/Hand Hygiene, p. 636
- Skill 32-2 Preparation of a Sterile Field, p. 650
- Skill 32-3 Surgical Handwashing/Hand Hygiene: Preparing for Gowning, p. 652
- Skill 32-4 Applying a Sterile Gown and Performing Closed Gloving, p. 655
- Skill 32-5 Open Gloving, p. 657
- Skill 33-1 Administering Oral Medications, p. 693
- Skill 33-2 Administering Ophthalmic Medications, p. 700
- Skill 33-3 Using Metered-Dose or Dry Powder Inhalers, p. 708
- Skill 33-4 Preparing Injections, p. 714
- Skill 33-5 Administering Injections, p. 722
- Skill 33-6 Adding Medications to Intravenous Fluid Containers, p. 727
- Skill 33-7 Administering Medications by Intravenous Bolus, p. 737
- Skill 33-8 Administering Intravenous Medications by Piggyback, Intermittent Intravenous Infusion Sets, and Mini-Infusion Pumps, p. 742
- Skill 36-1 Applying Physical Restraints, p. 815
- Skill 36-2 Seizure Precautions, p. 821
- Skill 37-1 Bathing a Patient, p. 843
- Skill 37-2 Performing Nail and Foot Care, p. 852
- Skill 37-3 Providing Oral Hygiene, p. 856
- Skill 37-4 Performing Mouth Care for an Unconscious or Debilitated Patient, p. 858
- Skill 37-5 Making an Occupied Bed, p. 868
- Skill 38-1 Suctioning, p. 905
- Skill 38-2 Care of an Artificial Airway, p. 913
- Skill 38-3 Care of Patients With Chest Tubes, p. 921
- Skill 38-4 Applying a Nasal Cannula or Oxygen Mask, p. 925
- Skill 38-5 Using Home Oxygen Equipment, p. 929
- Skill 39-1 Initiating a Peripheral Intravenous Infusion, p. 959
- Skill 39-2 Regulating Intravenous Flow Rates, p. 974
- Skill 39-3 Maintenance of Intravenous System, p. 978
- Skill 39-4 Changing a Peripheral Intravenous Dressing, p. 983
- Skill 42-1 Aspiration Precautions, p. 1072
- Skill 42-2 Blood Glucose Monitoring, p. 1082
- Skill 42-3 Inserting a Small-Bore Nasoenteric or Oral Tube for Enteral Feeding, p. 1088
- Skill 42-4 Administering Enteral Feedings via Nasoenteric Tube, p. 1093
- Skill 42-5 Administering Enteral Feedings via Gastrostomy or Jejunostomy Tube, p. 1097
- Skill 42-6 Inserting a Large-Bore Nasoenteric or Orogastic Tube for Gastric Suctioning, p. 1104
- Skill 43-1 Collecting a Midstream (Clean-Voided) Urine Specimen, p. 1125
- Skill 43-2 Inserting a Straight or In-Dwelling Catheter, p. 1139
- Skill 43-3 In-Dwelling Catheter Care, p. 1147
- Skill 43-4 Closed and Open Catheter Irrigation, p. 1149
- Skill 44-1 Administering a Cleansing Enema, p. 1182
- Skill 44-2 Pouching an Ostomy, p. 1189
- Skill 45-1 Moving and Positioning Patients in Bed, p. 1223
- Skill 45-2 Using Safe and Effective Transfer Techniques, p. 1233
- Skill 46-1 Assessment for Risk of Pressure Ulcer Development, p. 1254
- Skill 46-2 Treating Pressure Ulcers, p. 1278
- Skill 46-3 Applying Dry and Moist Dressings, p. 1282
- Skill 46-4 Performing Wound Irrigation, p. 1291
- Skill 46-5 Applying an Abdominal or Breast Binder, p. 1295
- Skill 46-6 Applying an Elastic Bandage, p. 1296
- Skill 48-1 Demonstrating Postoperative Exercises, p. 1343

Notice

Knowledge and best practice in this field are constantly changing. As new research and expertise broaden our knowledge, changes in practice, treatment, and drug therapy may become necessary or appropriate. Readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered and to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of the client, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions. To the fullest extent of the law, neither the Publisher nor the Authors assumes any liability for any injury and/or damage to persons or property arising out of or related to any use of the material contained in this book.

Unit I Health and Health Care in Canada

1 Health and Wellness, 1

Written by Linda Reutter, RN (Ret.), PhD, and
Kaysi Eastlick Kushner, RN, PhD

Conceptualizations of Health, 2

Classifications of Health Conceptualizations, 2

Historical Approaches to Health in Canada, 3

Medical Approach, 3

Behavioural Approach, 3

Socioenvironmental Approach, 4

Determinants of Health, 6

Income and Social Status (Income Distribution), 7

Social Support Networks, 7

Education and Literacy, 7

Employment and Working Conditions, 7

Physical Environments, 8

Biological and Genetic Endowment, 8

Individual Health Practices and Coping Skills, 8

Healthy Child Development, 9

Health Services, 9

Gender, 9

Culture, 10

Social Environments, 10

Strategies to Influence Health Determinants, 10

Health Promotion and Disease Prevention, 10

Health Promotion Strategies, 11

Population Health Promotion Model: Putting It All Together, 12

Summary, 13

2 The Canadian Health Care Delivery System, 15

Written by Pammla Lusenga Petrucka, RN, PhD

Evolution of the Canadian Health Care System, 16

Early Health Care in Canada, 16

Aboriginal Health Care, 18

Organization and Governance of Health Care, 19

Federal Jurisdiction, 19

Provincial and Territorial Jurisdiction, 19

Professional Jurisdiction, 19

Health Care Spending, 19

Trends and Reforms in Canada's Health Care System, 19

Role of Nurses in Health Care Policy, 20

Right to Health Care, 20

Rights Within the Health Care System, 20

Primary Health Care, 21

Barriers to Primary Health Care, 21

Future of Primary Health Care, 22

Settings for Health Care Delivery, 23

Institutional Sector, 23

Community Sector, 24

Levels of Care, 25

Level 1: Health Promotion, 25

Level 2: Disease and Injury Prevention, 25

Level 3: Diagnosis and Treatment, 25

Level 4: Rehabilitation, 25

Level 5: Supportive Care, 26

Challenges to the Health Care System, 26

Cost Accelerators, 26

Equality and Quality, 26

Nursing's Future in the Emerging Health Care System, 27

3 The Development of Nursing in Canada, 29

Written by Janet C. Ross-Kerr, RN, BScN, MS, PhD, and
Sonya Grypma, RN, PhD

Highlights of World Nursing History, 30

Early History of Nursing in Canada, 30

The First Nurses and Hospitals in New France, 30

The Birth of Home Visiting and the Grey Nuns, 31

Nursing During the British Regime, 31

Health Care in the West and the Grey Nuns, 31

The Nineteenth Century and Florence Nightingale, 32

Globalization and the Emergence of Modern Nursing, 33

Missionary Nursing, 33

Nursing in Remote Regions of Canada, 33

Gender and Diversity in Nursing, 34

Nursing Education in Canada, 34

The First Canadian Nursing Schools, 35

The Impact of Nursing Organizations on Nursing Education, 35

The Origins of the Canadian Nurses Association and Provincial Nursing Associations, 36

The First University Programs, 37

Health Care and Educational Reform, 37

The Weir Report, 37

The Royal Commission on Health Services of 1964, 37

Canadian Nurses Association Reports, 38

Baccalaureate Entry-to-Practice, 38

Influence of Periods of Social Upheaval on Nursing, 38

Public Health, Military Conflicts, and the Emergence of University Nursing Education, 38

From the Depression to the Post-World War II Years, 39

Emerging From Economic and Military Crises, 40

Nursing Education Today, 40

Conclusion, 40

4 Community Health Nursing Practice, 42

Written by Kaysi Eastlick Kushner, RN, PhD

Promoting the Health of Populations and Community Groups, 44

Community Health Nursing Practice, 44

Public Health Nursing, 45

Home Health Nursing, 45

The Changing Focus of Community Health Nursing Practice, 46

Vulnerable Populations, 47

Standards, Competencies, Roles, and Activities in Community Health Nursing, 50

Community Assessment, 51
Promoting Clients' Health, 52

Unit II Foundations of Nursing Practice

5 Theoretical Foundations of Nursing Practice, 54

Written by Sally Thorne, RN, PhD

Early Nursing Practice and the Emergence of Theory, 55

Nursing Process, 55

Conceptual Frameworks, 56

Metaparadigm Concepts, 56

Client and Person, 57

Environment, 57

Health, 57

Nursing, 58

Philosophy of Nursing Science, 58

Scientific Revolutions, 58

Complexity Science, 58

Ways of Knowing in Nursing Practice, 58

Paradigm Debates Within Nursing, 58

Nursing Diagnosis, 59

Reflections on Conceptualizing Nursing, 59

Major Theoretical Models, 59

Practice-Based Theories, 60

Needs Theories, 60

Interactionist Theories, 61

Systems Theories, 61

Simultaneity Theories, 62

Theorizing in the Future, 62

6 Research as a Basis for Practice, 65

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by Marilyn J. Wood, BSN, MSN, DrPH, and Wendy Duggleby, RN, PhD, AOCN

Why Evidence?, 66

Researching the Evidence, 66

Ask the Clinical Question, 66

Collect the Best Evidence, 67

Critique the Evidence, 68

Integrate the Evidence, 69

Evaluate the Practice Decision or Change, 70

Support for Evidence-Informed Practice, 70

Knowledge Development in Nursing, 70

Empirics: The Science of Nursing, 70

Esthetics: The Art of Nursing, 70

Personal Knowledge, 70

Ethics: The Moral Component, 71

Emancipatory Knowing: The Social, Economic, and Political Component, 71

The Development of Research in Nursing, 71

The History of Nursing Research in Canada, 71

Nursing Research, 73

The Scientific Paradigm, 73

The Qualitative (Interpretive) Paradigm, 74

Research Designs, 74

Quantitative Nursing Research, 74

Qualitative Nursing Research, 75

Conducting Nursing Research, 77

Ethical Issues in Research, 77

Rights of Other Research Participants, 77

Applying Research Findings to Nursing Practice, 78

7 Nursing Values and Ethics, 80

Canadian content written by Shelley Raffin Bouchal, RN, PhD

Based on original chapter by Margaret Ecker, RN, MS

Values, 81

Values Formation, 81

Values Clarification, 81

Ethics, 82

Nursing and Ethics, 82

Ethical Theory, 84

Ethical Analysis and Nursing, 86

Ethical Issues in Nursing Practice, 88

Patient Care Issues, 88

Issues of Safety in the Work Environment, 90

8 Legal Implications in Nursing Practice, 94

Written by Carla Shapiro, RN, MN

Based on the original chapter by Christine R. Durbin, RN, PhD, JD

Legal Limits of Nursing, 94

Sources of Law, 95

Professional Regulation, 95

Regulation of Nurse Practitioners, 95

Standards of Care, 95

Legal Liability Issues in Nursing Practice, 97

Torts, 97

Intentional Torts, 97

Unintentional Torts, 98

Criminal Liability, 99

Consent, 99

Nursing Students and Legal Liability, 100

Professional Liability Protection, 101

Abandonment, Assignment, and Contract Issues, 101

Legal Issues in Nursing Practice, 102

Abortion, 102

Drug Regulations and Nurses, 102

Communicable Diseases, 103

Death and Dying, 103

Advance Directives and Health Care Surrogates, 104

Organ Donation, 104

Mental Health Issues, 104

Public Health Issues, 104

Risk Management, 105

Professional Involvement, 105

9 Global Health, Culture, and Diversity, 107

Written by Barbara J. Astle, RN, PhD, Sylvia S. Barton, RN, PhD, Leanne Johnson, RN, MN, and Judy Mill, RN, PhD

Global Health, 107

Health Equity, 108

Global Citizenship, 108

Cultural Diversity, 109

Understanding Cultural Concepts, 110

Cultural Conflicts, 111

Historical Development of the Concept of Culture, 111

Cultural Assessment, 114**Selected Components of Cultural Assessment, 116**

- Ethnohistory, 116
- Social Organization, 116
- Socioeconomic Status, Biocultural Ecology, and Health Risks, 118
- Language and Communication, 118
- Religion and Spirituality, 118
- Caring Beliefs and Practices, 118
- Experience With Professional Health Care, 119

Application of Cultural Assessment Components to Aboriginal Peoples of Canada, 119

- Ethnohistory, 119
- Social Organization, 120
- Socioeconomic Status, 120
- Biocultural Ecology and Health Risks, 120
- Language and Communication, 121
- Religious and Spiritual Practices, 121
- Caring Beliefs and Practices, 122
- Experience With Professional Health Care, 122
- Implications for Nursing Practice, 122

10 Nursing Leadership, Management, and Collaborative Practice, 125

Written by Susan M. Duncan, RN, PhD

Management and Leadership Roles for Nurses, 126

- Nursing Care Delivery Models, Collaborative Practice, and Nursing Teams, 126
- Decision Making, 130
- Clinical Care Coordination, 133

Quality Care and Patient Safety, 135

- Quality in Nursing Practice, 135
- Building a Culture of Safety, 135

Leadership Skills for Nursing Students, 136

- Career Development and Mentoring for Nursing Students, 136

Unit III Approaches to Nursing Care**11 Critical Thinking in Nursing Practice, 140**

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN
Canadian content written by Donna M. Romy, RN, PhD

Critical Thinking Defined, 141**A Critical Thinking Model for Clinical Decision Making, 141****Levels of Critical Thinking in Nursing, 142**

- Basic Critical Thinking, 142
- Complex Critical Thinking, 142
- Commitment, 143

Components of Critical Thinking in Nursing, 143

- Specific Knowledge Base, 143
- Experience, 144

Critical Thinking Competencies, 144

- General Critical Thinking Competencies, 144
- Specific Critical Thinking Competencies in Clinical Situations, 145
- Nursing Process as a Critical Thinking Competency, 147
- Attitudes for Critical Thinking, 147
- Standards for Critical Thinking, 148

Developing Critical Thinking Skills, 148

- Reflective Journal Writing, 148
- Concept Mapping, 149

Critical Thinking Synthesis, 149**12 Nursing Assessment and Diagnosis, 153**

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN
Canadian content written by S. Helen Fraser, RN, MN,

- Debbie A. Brennick, RN, MN, and
- Willena I. Nemeth, RN, MN

Critical Thinking Approach to Assessment, 154**Data Collection, 155**

- Types of Data, 156
- Sources of Data, 156
- Methods of Data Collection, 158
- Cultural Considerations in Assessment, 160
- Nursing Health History, 160
- Family History, 160
- Documentation of History Findings, 160
- Physical Examination, 160
- Data Documentation, 162
- Concept Mapping, 162

Nursing Diagnosis, 162**Critical Thinking and the Nursing Diagnostic Process, 165**

- Formulation of the Nursing Diagnosis, 166
- Components of a Nursing Diagnosis, 166

Concept Mapping for Nursing Diagnoses, 168**Sources of Diagnostic Errors, 169**

- Errors in Data Collection, 170
- Errors in Interpretation and Analysis of Data, 170
- Errors in Data Clustering, 170
- Errors in the Diagnostic Statement, 170
- Documentation, 170

Nursing Diagnoses: Application to Care Planning, 170**13 Planning and Implementing Nursing Care, 173**

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN
Canadian content written by Willena I. Nemeth, RN, MN,

- S. Helen Fraser, RN, MN, and Debbie A. Brennick, RN, MN

Planning Nursing Care, 173**Establishing Priorities, 174****Critical Thinking in Establishing Goals and Expected Outcomes, 175**

- Goals of Care, 176
- Expected Outcomes, 177
- Combining Goals and Outcome Statements, 177
- Guidelines for Writing Goals and Expected Outcomes, 177

Types of Interventions, 178**Selection of Interventions, 178**

- Nursing Interventions Classification, 179

Planning Nursing Care, 182

- Institutional Care Plans, 182
- Concept Maps, 182

Consulting Other Health Care Professionals, 184

- Implementing Nursing Care, 185

Critical Thinking in Implementation, 185**Standard Nursing Interventions, 185**

- Clinical Practice Guidelines and Protocols, 185
- Medical Directives or Standing Orders, 186
- Nursing Intervention Classifications System, 186

Implementation Process, 186

- Reassessing the Client, 187
- Reviewing and Revising the Existing Nursing Care Plan, 187
- Organizing Resources and Care Delivery, 187
- Anticipating and Preventing Complications, 187
- Implementation Skills, 188

Direct Care, 189

- Activities of Daily Living, 189
- Instrumental Activities of Daily Living, 189
- Physical Care Techniques, 189
- Life-Saving Measures, 189
- Counselling, 189
- Teaching, 189
- Controlling for Adverse Reactions, 190
- Preventive Measures, 190

Indirect Care, 190

- Communicating Nursing Interventions, 190
- Delegating, Supervising, and Evaluating the Work of Other Staff Members, 190

Achieving Client-Centred Goals, 190**14 Evaluation of Nursing Care, 193**

- Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN
- Canadian content written by Debbie A. Brennick, RN, MN, Willena I. Nemeth, RN, MN, and S. Helen Fraser, RN, MN

Critical Thinking and Evaluation, 194**The Evaluation Process, 195**

- Identifying Criteria and Standards, 195
- Collecting Evaluative Data, 196
- Interpreting and Summarizing Findings, 197
- Documenting Findings, 198
- Care Plan Revision, 198
- Discontinuing a Care Plan, 199
- Modifying a Care Plan, 199
- Goals and Expected Outcomes, 199
- Interventions, 199

15 Documenting and Reporting, 202

- Original chapter by Frank Lyerla, RN, PhD
- Canadian content written by Maureen A. Barry, RN, MSCN

Confidentiality, 203

- Personal Information Protection and Electronic Documents Act, 203

Multidisciplinary Communication Within the Health Care Team, 203**Purposes of Records, 204**

- Communication and Care Planning, 204
- Legal Documentation, 204
- Education, 204
- Funding and Resource Management, 206

Research, 206

Auditing-Monitoring, 206

Guidelines for Quality Documentation and Reporting, 206

- Factual, 206
- Accurate, 206
- Complete, 207
- Current, 208
- Organized, 208
- Compliant With Standards, 208

Common Documentation Systems, 208

- Narrative Documentation, 208
- Problem-Oriented Medical Records or Health Care Records, 208
- Source Records, 209
- Charting by Exception, 210
- Case Management Plan and Critical Pathways or Care Maps, 210

Common Record-Keeping Forms, 213

- Admission Nursing History Forms, 213
- Flow Sheets and Graphic Records, 213
- Patient Care Summary or Kardex, 213
- Acuity Records or Workload Measurement Systems, 219
- Standardized Care Plans, 219
- Discharge Summary Forms, 219

Home Health Care Documentation, 220**Long-Term Health Care Documentation, 220****Computerized Documentation, 220**

- Nursing Information Systems, 222
- Clinical Information Systems, 223

The Electronic Health Record, 223**Reporting, 223**

- Change-of-Shift Reports, 223
- Telephone Reports, 225
- Telephone or Verbal Orders, 225
- Transfer Reports, 225
- Incident Reports, 225

16 Nursing Informatics and Canadian Nursing Practice, 228

- Written by Kathryn J. Hannah, RN, PhD, and Margaret Ann Kennedy, RN, PhD, CPHIMS-CA

Nursing Informatics and the Canadian Health Care System, 229

- Defining Nursing Informatics, 229
- Evolution of Informatics in the Canadian Health Care System, 229

Standards in Health Informatics, 231

- Standards Development in Canada, 233
- Standardizing Nursing Language, 233
- Health Information: Nursing Components, 233
- International Classification for Nursing Practice®, 233

Canadian Privacy Legislation, 235**National e-Nursing Strategy, 237****Clinician Engagement and Informatics Communities, 239**

Unit IV Working With Patients and Families

17 Communication, 242

Written by Sonya L. Jakubec, RN, MN, PhD(c), and
Barbara J. Astle, RN, PhD

Communication and Interpersonal Relationships, 243

Developing Communication Skills, 243

Levels of Communication, 244

- Intrapersonal Communication, 244
- Interpersonal Communication, 245
- Transpersonal Communication, 245
- Small-Group Communication, 245
- Public Communication, 245

Basic Elements of the Communication Process, 245

- Referent, 245
- Sender and Receiver, 245
- Messages, 245
- Channels, 246
- Feedback, 246
- Interpersonal Variables, 246
- Environment, 246

Forms of Communication, 246

- Verbal Communication, 246
- Nonverbal Communication, 247
- Symbolic Communication, 248
- Metacommunication, 248

Professional Nursing Relationships, 248

- Nurse–Patient Helping Relationships, 248
- Nurse–Family Relationships, 250
- Interprofessional Team Relationships, 250
- Nurse–Community Relationships, 250

Elements of Professional Communication, 250

- Courtesy, 250
- Use of Names, 250
- Trustworthiness, 250
- Autonomy and Responsibility, 251
- Assertiveness, 251

Communication Within the Nursing Process, 251

- Assessment, 251
- Nursing Diagnosis, 253
- Planning, 253
- Implementation, 253
- Evaluation, 258

18 Caring in Nursing Practice, 262

Original chapter by Anne Griffin Perry, RN, EdD, FAAN
Canadian content written by Cheryl Sams, RN, MSN

Theoretical Views on Caring, 263

- Caring Is Primary, 263
- The Essence of Nursing and Health, 264
- Transpersonal Caring, 264
- Swanson's Theory of Caring, 264
- The Human Act of Caring, 265
- The Moral and Ethical Bases of Responsive Nurse–
Patient Relationships, 266
- Summary of Theoretical Views, 266

Patients' Perceptions of Caring, 267

Ethic of Care, 267

Caring in Nursing Practice, 268

- Providing Presence, 268
- Touch, 268
- Listening, 269
- Knowing the Patient, 269
- Spiritual Caring, 270
- Family Care, 270

The Challenge of Caring, 270

19 Family Nursing, 273

Written by Christina West, RN, PhD, and Sonya L. Jakubec,
RN, MN, PhD(c)

What Is a Family?, 274

Current Trends in the Canadian Family, 274

- Family Forms, 274
- Family Changes and Challenges: Understanding the
Influence of Sociocultural Contexts, 275

Teenage Pregnancy, 275

- Domestic Roles, 275
- Economic Status, 275
- Aboriginal Families, 275
- Family Caregivers, 275

The Family and Health, 276

- Attributes of Healthy Families, 276

Family Nursing Care, 277

- Family as Context, 277
- Family as Patient, 277
- Understanding Family in Context: Family Nursing as
Relational Inquiry, 277

Assessing the Challenges, Strengths, and Needs of the Family: The Calgary Family Assessment Model, 278

- Structural Assessment, 279
- Developmental Assessment, 282
- Functional Assessment, 282

Family Intervention: The Calgary Family Intervention Model, 284

- Asking Interventive Questions, 284
- Offering Commendations, 285
- Providing Information, 286
- Validating or Normalizing Emotional Responses, 286
- Encouraging Illness Narratives, 286
- Encouraging Family Support, 286
- Supporting Family Caregivers, 287
- Encouraging Respite, 287

Interviewing the Family, 287

20 Patient Education, 290

Original chapter by Amy M. Hall, RN, BSN, MS, PhD, CNE
Canadian content written by Nancy A. Edgecombe, RN-NP,
BN, MN, PhD

Goals of Patient Education, 291

- Maintaining and Promoting Health and Preventing
Illness, 291
- Restoring Health, 291
- Coping With Impaired Functioning, 291

Teaching and Learning, 292

- Role of the Nurse in Teaching and Learning, 292
- Teaching as Communication, 293

Domains of Learning, 293

- Cognitive Learning, 293
- Affective Learning, 294
- Psychomotor Learning, 294

Basic Learning Principles, 294

- Learning Environment, 294
- Ability to Learn, 294
- Learning Style and Preference, 295
- Motivation to Learn, 296

Integrating the Nursing and Teaching Processes, 297

- Assessment, 297
- Nursing Diagnosis, 298
- Planning, 299
- Implementation, 301
- Evaluation, 306

Unit V Caring Throughout the Lifespan**21 Developmental Theories, 309**

- Original chapter by Karen Balakas, RN, PhD, CNE
- Canadian content written by Nicole Letourneau, RN, PhD

Growth and Development, 310

- Physical Growth, 310
- Development, 310
- Factors Influencing Growth and Development, 310

Traditions of Developmental Theories, 310**Organicism, 311**

- Biophysical Developmental Theories, 311
- Cognitive Developmental Theories, 313
- Moral Developmental Theories, 313

Psychoanalytic and Psychosocial Tradition, 315

- Sigmund Freud, 315
- Erikson's Theory of Eight Stages of Life, 317
- John Bowlby, 319
- Patricia Crittenden, 319
- Havighurst's Developmental Tasks, 320

Mechanistic Tradition, 321**Contextualism, 321**

- Bioecological Theory, 321

Dialecticism, 322

- Keating and Hertzman's Population Health Theory, 322
- Resilience Theory, 323

Developmental Theories and Nursing, 323**22 Conception Through Adolescence, 326**

- Original chapter by Karen Balakas, RN, PhD, CNE
- Canadian content written by Cynthia Murray, BN, MN, PhD

Selecting a Developmental Framework for Nursing, 327**Conception, 327**

- Intrauterine Life, 327
- Health Promotion, 328

Transition From Intrauterine to Extrauterine Life, 328

Preface to the Student

Canadian Fundamentals of Nursing provides you with all of the fundamental nursing concepts and skills you will need in a visually appealing, easy-to-use format. As you begin your nursing education, it is very important that you have a resource that includes all of the information required to prepare you for lectures, classroom activities, clinical assignments, and examinations. We've designed this text to meet all of those needs.

Check out the following special learning aids featured in *Canadian Fundamentals of Nursing*.

Learning Objectives begin each chapter to help you focus on the key information that follows.

1 Health and Wellness

Written by Linda Reutter, RN (Ret.), PhD, and Kaysi Eastlick Kushner, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss ways that definitions of health have been conceptualized.
- Describe key characteristics of medical, behavioural, and socioenvironmental approaches to health.
- Identify factors that have led to each approach to health.
- Discuss contributions of the following Canadian publications to conceptualizations of health and health determinants: *Lalonde Report*, *Ottawa Charter*, *Epp Report*, *Strategies for Population Health*, *Jakarta Declaration*, *Bangkok Charter*, *Toronto Charter*.
- Discuss key health determinants and their interrelationships and how they influence health.
- Contrast distinguishing features of health promotion and disease prevention.
- Describe the three levels of disease prevention.
- Identify and give examples of the five health promotion strategies discussed in the *Ottawa Charter*.
- Analyze how the nature and scope of nursing practice are influenced by different conceptualizations of health and health determinants.

Key Terms are listed at the beginning of each chapter and are boldfaced and defined in the text. Page numbers help you quickly find where each term is defined.

key terms

- Behavioural approach, p. 3
- Behavioural risk factors, p. 3
- Determinants of health, p. 7
- Disease, p. 2
- Disease prevention, p. 10
- Health, p. 2
- Health as actualization, p. 2
- Health as actualization and stability, p. 2
- Health as stability, p. 2
- Health disparities, p. 6
- Health field concept, p. 3
- Health promotion, p. 10
- Health promotion strategies, p. 11
- Population health approach, p. 5
- Prerequisites for health, p. 4
- Psychosocial risk factors, p. 4
- Social determinants of health, p. 6
- Socioenvironmental approach, p. 4
- Socioenvironmental risk conditions, p. 4
- Wellness, p. 2

Evolve Resources detail what electronic resources are available to you for every chapter.

Concepts of health and what determines health have changed significantly since the 1970s. This conceptual change has major implications for Canadian nursing in the twenty-first century because how you perceive health—and what determines it—influences the nature and scope of nursing practice. The importance of health to nursing is reflected in nursing models and frameworks, in which health is one of the “metaparadigm” concepts along with *person*, *environment*, *nursing*, and, more recently, *social justice* (see Chapter 4). In each framework, health concepts are congruent with the assumptions and focus of the model.

✦ REVIEW QUESTIONS

- Canada has undertaken an effort to reduce wait times, reduce duplication of tests, and support coordination of care through which agency?
 1. Canada e-Health
 2. Canada Infloway
 3. Canada m-Health
 4. Electronic Health Records
2. Which of the following people are insured under the *Canada Health Act*?
 1. Aboriginal peoples
 2. RCMP members
 3. Members of military services
 4. Persons in transit between provinces
3. Public health focuses on
 1. Treatment
 2. Promotion
 3. Intervention
 4. Institutionalization
4. The *Canada Health Act* embraces the following five principles:
 1. Public administration, comprehensiveness, universality, portability, accessibility
 2. Social justice, equity, acceptability, efficiency, effectiveness
 3. Accountability, equality, economy, collaboration, coordination
 4. Insured health services, provider compensation, hospital services, community care, and pharmaceuticals
5. An adult day support program is an example of a(n)
 1. Home care agency
 2. Institutional agency
 3. Community agency
 4. Ambulatory care centre
6. What are the five levels of health care services?
 1. Promotive, preventive, curative, rehabilitative, supportive
 2. Prevention, protection, diagnosis, treatment, palliative care
 3. Promotion, prevention, treatment, PHC, diagnosis
 4. Assessment, diagnosis, planning, implementation, evaluation
7. Which trend is most critical in the future health human resources planning?
 1. Keeping sufficient physicians
 2. Ensuring adequate providers in rural and remote areas
 3. Ensuring ethical recruitment and retention
 4. Increasing number of health providers to respond to emerging health needs
8. Which is not a cause of Canada's increasing health care costs?
 1. Workplace injuries
 2. Aging population
 3. New technologies and pharmaceuticals
 4. Chronic and emerging diseases

9. A nurse organizes a blood pressure screening program as a _____ strategy.
1. Health promotion
 2. Disease prevention
 3. Continuing care
 4. Rehabilitation
10. Provision of specialized medical services by a physician specialist or a hospital is _____.
1. Primary care
 2. Primary health care
 3. Secondary care
 4. Tertiary care

This site addresses initiatives of the foundation that relate to PHC reform and research.

Canada Health Infoway: <https://www.infoway-inforoute.ca/>

A not-for-profit corporation created by Canada's First Ministers to foster and accelerate development and adoption of EHR systems with compatible standards and communication technologies.

Canadian Institute of Health Information: <http://www.cihi.ca>
A not-for-profit organization seeking to improve the health care system and the health of Canadians by providing health information.

Canadian Public Health Association: <http://www.cpha.ca>

A national, not-for-profit association seeking excellence in public health nationally and internationally.

Health Canada: <http://www.hc-sc.gc.ca>

This site provides links to information about the Canadian health care system, such as the *Canada Health Act* legislation, and federal reports.

Canadian Patient Safety Institute: <http://www.patient-safetyinstitute.ca>

This institute was established to build and advance a safer health care system for Canadians. It reports on activities in leadership across health sectors and health care systems, highlights promising practices, and raises awareness with stakeholders and the public about patient safety.

Health Quality Council (Saskatchewan): <http://www.hqc.sk.ca>
The Saskatchewan Health Quality Council was established in 2002 through provincial legislation to improve health care in Saskatchewan by encouraging the use of best evidence.

Health Council of Canada: <http://www.healthcouncilcanada.ca/>
The Health Council of Canada fosters accountability and transparency by assessing, monitoring, and reporting progress in improving quality, effectiveness, and sustainability of the health care system for the well-being of Canadians.

Review Questions Answers

1. 2; 2. 4; 3. 2; 4. 1; 5. 3; 6. 1; 7. 3; 8. 1; 9. 2; 10. 3

Rationales for the Review Questions appear at the end of the book.

diverse range of environments, a situation that challenges quality issues and affects recruitment and retention. Sustainable and quality workforces, organizational efficiencies, and improved patient care are related to improved work environments (Health Canada, 2010c). The Pan-Canadian Health Human Resource Strategy (PC HHRS) articulates approaches to enhancing work and learning conditions necessary to maintain an experienced, dedicated and skilled workforce for high quality, safe, and timely care (Health Canada, 2010c).

Privatization of Services. Governments are struggling to maintain the principle of universality against the benefits and challenges of privatization. At present, not all health care services are available and accessible to all Canadians. For example, infertility treatments and laser eye surgical procedures are performed in private offices, available to clients who can afford them. Discussions persist about what constitutes "medically necessary services" and what makes up universal "core services," with many experts contending that the survival of medicare depends on privatizing more parts of the health care system.

Health Care Human Resources. In 2006, more than 1 million people (about 6% of the total workforce) in Canada worked directly in health-related occupations (Chui et al., 2007). Despite these numbers, accessibility to health care services is compromised by shortages of physicians, nurses, and other health care professionals. Health Canada (2010c) states health and human resources planning must occur within the broader health care system, recognizing systemic challenges of wait times, patient safety, and bed closures.

Aboriginal peoples are significantly under-represented in health professions. Health Canada established a five-year initiative, known as the Aboriginal Health Human Resources Initiative (AHHRI), focusing on increasing Aboriginal representation in health professions and retention of health care providers successfully working with Aboriginal peoples as part of the PC HHRS. The AHHRI-Phase II was extended in December 2010.

Review Questions at the end of each chapter help you review and evaluate what you have learned. Answers and rationales are provided at the back of the book.

Key Concepts appear at the end of each chapter to help you review important content.

The Canadian Health Care Delivery System 27

Nursing's Future in the Emerging Health Care System

This chapter provided extensive discussion about restructuring and challenges within the Canadian health care system. Within the context of restructuring and complexities within the Canadian system, nursing roles continue to evolve and diversify. In the future, nurses will increasingly be regarded as critical stakeholders, partners, and providers within the emerging health care system. Nurses will continue to draw on their historical legacy, forge ahead, and use evidence to inform their pursuit of excellence and quality in care, while advocating and innovating for the benefit of their clients.

KEY CONCEPTS

- Medicare is a key component of Canada's social safety net.
- Government plays a major role in the Canadian health care system by co-funding national health insurance and by setting health care policy in accordance with the *Canada Health Act*.
- The *Canada Health Act* forbids extra billing and user fees while articulating the principles of public administration, comprehensiveness, universality, portability, and accessibility.
- Health care services are provided in institutional, community, and home settings; across all age groups; and for individual, family, group, community, and population clients.
- Five levels of health care are promotive, preventive, curative, rehabilitative, and supportive.
- Escalating costs and consumer expectations challenge the health care system to seek and deliver innovative, efficient, and quality care.
- Issues of equality, access, interprofessional approaches, and continuity of care challenge the health care system.
- The rise of PHC and home care is a result of health care reforms.
- Successful health promotion and disease prevention programs help clients achieve healthier lifestyles and achieve a decent standard of living.
- Demographic, geographical, and technological realities affect the functioning and restructuring of the Canadian health care system.
- The existence of sufficient, diverse, and qualified human health resources is a key challenge to the Canadian health care system.
- Enhancing the health of Aboriginal peoples in Canada is a significant challenge to society and to the health care system.
- Nurses must continually seek out information and evidence to remain responsive to providing quality, culturally competent, and safe care.

CRITICAL THINKING EXERCISES

1. Debate the following issues respecting the future of the Canadian health care system: escalating costs, privatization, continuity of care, electronic health records.
2. Consider and describe how the national economy and technology have changed the Canadian health care system. What are the implications for nursing?
3. Mr. W., a 68-year-old widower with no immediate family supports, is scheduled to have major surgery to replace the joint in his hip. He is generally in good health and lives in a seniors-only apartment complex in the centre of town. After surgery, he will need extensive therapy in order to walk. Describe the types of health care services, patient safety issues, and technological supports that might play a part in his care.

Critical Thinking Exercises encourage you to think creatively and effectively to apply essential content.

Figure 35-9 Critical thinking model for activity and exercise evaluation.

- The best program of physical activity includes a combination of exercises that produce different physiological and psychological benefits.
- Coordinated body movement to move, lift, bend, stand, sit, lie down, and complete daily activities requires integrated functioning of the skeletal system, skeletal muscles, and nervous system.
- Muscles primarily associated with movement are located near the skeletal region, where movement results from leverage, which is characteristic of the upper extremities.
- Coordination and regulation of muscle groups depend on muscle tone and activity of antagonistic, synergistic, and anti-gravity muscles.
- Balance is assisted by nervous system control in the cerebellum and by inner ear function.
- Body balance is achieved when a wide base of support exists, the centre of gravity is within the base of support, and the centre of gravity is vertically aligned with the base of support.
- Developmental changes, behavioural aspects, environmental issues, cultural and ethnic influences, and family and social support affect the patient's perception of and motivation to engage in physical activity and exercise.
- Ability to engage in normal physical activity and exercise depends on intact and functioning nervous and musculoskeletal systems.
- Use the nursing process to provide care for patients who are experiencing or are at risk for activity intolerance and impaired physical mobility.

BOX 35-16 NURSING STORY

Activity and Exercise

I have been in nursing for over 40 years. For more than 30 years of that time, before moving into teaching, I worked as a hospital staff nurse providing direct care to patients. I worked mainly in areas where patients were unable to assist themselves very much, such as in the birthing and critical care units. As is the case with most nurses, the wear and tear of lifting, turning, and transferring patients took a toll on my body, primarily on my back, knees, and feet. But for as long as it was part of my role, I was able to do work.

Several years later, after I began teaching a nursing fundamentals course, my physical activity related to nursing consisted of demonstrating fundamental skills in the laboratory setting and of providing assistance to students with their practice. During my fifth year of teaching that course, I was taken by surprise at how difficult I found it to lift, position, or transfer my volunteer "patients," and at how extremely tired and sore I was at the end of each day. What was happening to me?

Upon reflection, I realized that two factors were involved. The first was normal change resulting from aging: the decrease in strength and endurance that occurs after age 40 among women. The second factor was the relatively sedentary lifestyle I had led since I had left bedside nursing. Mine was a classic case of functional decline from disuse, a major concern as aging occurs. As I thought further about it, I remembered that I had noticed groceries becoming heavier and stair climbing feeling more difficult. At the rate I was changing, I had little hope of maintaining my independence well into old age. In the shorter term, if I expected to keep teaching for a few more years, I would need to do something about my fitness level quickly!

My strategies? To use my gym membership (neglected for months and never attended routinely) four times per week from June through August and at least three times per week throughout the academic year, and to walk for no less than 30 minutes every day. No more avoiding stairs, either! I decided to walk up one floor and down two

The unique **Critical Thinking Model** clearly shows how the nursing process and critical thinking come together to help you provide the best care for your patients.

Concept Maps show you the association among multiple nursing diagnoses and their relationship to medical diagnoses.

Figure 26-4 Concept map for a patient with depression after the death of his wife.

As a result of the patient's medical condition, associated health problems include the nursing diagnoses *dysfunctional grieving*, *disturbed sleep pattern*, and *imbalanced nutrition: less than body requirements*. You must determine which of the three diagnoses necessitates greater attention. The continuing grief experienced by the patient might be the focus. Until the patient is able to accept his loss and begin resolving his grief, he may be unable to attend to interventions that will improve his nutritional intake and sleep status.

Patients' conditions always change. In the ongoing assessment of a patient's condition, you can quickly discover a new problem. You must always consider which of the patient's most urgent physical or psychological needs require immediate intervention. You consider the patient's expectations and preferences in regard to the priorities of care. If a terminally ill patient's priorities include controlling pain and maintaining self-esteem, pain control is the priority when analgesics become ineffective and the patient experiences acute distress. If the patient is progressing as desired, you may refocus priorities to address unmet needs. For example, the patient suffering depression caused by his wife's death also has problems of imbalanced nutrition and disturbed sleep pattern. If the patient reports improved appetite and has shown weight stabilization since the last clinic visit, you can focus more attention on the sleep pattern disturbance. You must remember that the patient's expectations, clinical condition, and preferences influence priorities. If a terminally ill patient places more emphasis on spiritual support than on other priorities such as learning about planned treatments, you must attend to the patient's priorities. Meeting patient priorities may allow you to then address other needs more effectively with less effort.

Continuity of Care

Primary teams help identify and meet the needs of patients experiencing losses. Dietitians, clergy, physicians, nurses, physiotherapists, psychologists, chaplains, and other health care providers can assist a patient and

family in their grief. A coordinated team approach to managing a patient's needs results in a well-managed care plan. When a patient dies, the loss that you and your colleagues experience can be shared within the interprofessional group. Support is needed to promote healing for all who worked with the dying patient and the family. Conflicts and differences can be discussed openly and solutions found in a healthy manner with the patient as the primary focus. For example, ethical conflicts may have arisen related to proposed or performed medical treatments or interventions. Through working together, the sharing of experiences, feelings, alternatives, and solutions becomes the basis for dealing with future losses.

Many terminally ill patients return home and require continued intensive nursing care. Home care nurses collaborate closely with family members to meet the patient's ongoing needs. Important interventions to include in planning a return home are arranging for main-floor access, arranging appropriate medical equipment, and providing sufficient family respite. When it is realistic for the patient to remain independent, therapeutic strategies should bolster the patient's sense of autonomy and the ability to function as independently as possible (Smith & Kautz, 2007). For example, judicious application of orthotic devices, along with physiotherapy and occupational therapy, can often bolster a patient's functional capacity. In the home, safety issues related to the environment may exist, and patients often benefit from nurse-initiated referrals to community occupational therapists.

Implementation

Health Promotion

Although a return to full function is not an expected outcome for a terminally ill patient or even for a patient who has significant disability, optimal physical and emotional functioning is a realistic goal. The goal of nursing care is to help patients and families cope with the stressors in their lives and to achieve healthy grief resolution. You help patients and families in

The five-step **Nursing Process** provides a consistent framework for presentation of content in clinical chapters.

In Canada, the CNA (2010a) advocates in its position statement that culturally competent care can and should be practised in all clinical settings. The "underlying values for cultural competence are inclusivity, respect, valuing differences, equity and commitment" (Registered Nurses' Association of Ontario, 2007, p. 19). Cultural competence is viewed as a key concept in the application of knowledge, skill, attitudes, and personal attributes by nurses in the provision of appropriate care and services in relation to the cultural characteristics of patients. A nurse practising in this way, for instance, would hold the belief of valuing diversity, be interested in and seek out knowledge as appropriate about cultural mores and traditions from diverse patients being served, and be sensitive to these while caring for the cultural diverse person. Although nurses are responsible for providing culturally competent care, nursing regulatory bodies, professional associations, educational institutions, governments, health service agencies, and accreditation organizations share the responsibility of supporting culturally competent care. You are in a position to build partnerships with other health care providers, patients, and funding agencies in order to establish culturally diverse practices that optimize patients' health outcomes.

The provision of culturally competent care has been promoted since the 1960s. Only since 2000, however, have Canadian nurse scholars begun to question the limitations of such an approach (Anderson et al., 2003; Kirkham, 2003) and to examine, critically, the concept of **cultural safety** as another approach to providing care to diverse groups, in contrast to the conceptual notion of transcultural nursing (Ramsden, 2002). The College of Registered Nurses of British Columbia's (2006) profile of newly graduated registered nurse practice focuses on the therapeutic caring and culturally safe relationships between patients and health care team members. The cultural safety literature is framed within a critical social theory and postcolonial framework. The concept of cultural safety evolved over a number of years in New Zealand, as nurses tried to identify a way in which health care providers could more effectively address the inequity in the health status of Maori people. This was combined with an analysis of the historical, political, social, and economic situations influencing the health of Maori people (Ramsden, 2002). Cultural safety involves considering the redistribution of power and resources in a relationship. The notion "is based on the premise that the term 'culture' is used in its broadest sense to apply to any person or group of people who may differ from the nurse, midwife because of socio-economic status, age, gender, sexual orientation, ethnic origin, migrant/refugee status, religious belief or disability" (Ramsden, 2002, Chapter 8, p. 3). In contrast to transcultural nursing, the term *culture* refers to ethnicity. As a result, the philosophy of cultural care has shifted from a notion of cultural sensitivity underpinning the provisions of care irrespective of culture to one of cultural safety with the recognition of power imbalances, the understanding of the nature of interpersonal relationships, and the awareness of institutional discrimination (Baker, 2007; Browne & Finkle, 2001; Brown et al., 2009; CNA, 2010a; Racine, 2009) (Box 9-3). Thus, understanding and providing culturally competent and safe care have the potential to make a difference to the health of many culturally diverse groups, especially Canada's Aboriginal population of First Nations, Inuit, and Métis peoples.

Ramsden (2002) articulated that *cultural awareness* and *cultural sensitivity* are separate concepts and that those terms are not interchangeable with *cultural safety*. Achieving cultural

BOX 9-3 RESEARCH HIGHLIGHT

Globalization and the Cultural Safety of an Immigrant Muslim Community

Research Focus

The social health of Muslims who reside in smaller areas of Canada is not clearly understood by health care providers. The concept of cultural safety has been used in studies of both Aboriginal peoples and immigrants in a large metropolitan centre, but the dichotomy between culturally safe and unsafe groups was found to be blurred. To further understand the concept of cultural safety, Baker (2007) focused on the social health of a small immigrant community of Muslims in a relatively homogeneous region of Canada after the terrorist attacks in the United States on September 11, 2001 ("9/11").

Research Abstract

Many Muslims living in North America and Western Europe were negatively affected by the events of 9/11. A qualitative approach based on the constructivist paradigm was used to guide the study, and 26 in-depth interviews were conducted with Muslims (10 women and 16 men) of Middle Eastern, Pakistani, or Indian origin. The participants resided in the province of New Brunswick, Canada, between 2002 and 2003. Data collection and analysis were conducted simultaneously. Steps of utilizing, categorizing, and pattern seeking were used to dissect the interviews until saturation was obtained. Many participants reported that after 9/11, their Islamic faith and experiences of being Muslim suddenly became significant to society at large. The research findings revealed that these participants talked about a sudden transition from cultural safety to cultural risk after 9/11. Their positive experiences of cultural safety included invisibility as a minority and a sense of social integration in the community. Cultural risk was found to stem from intensive international media attention that highlighted their precarious minority status.

Research Highlight boxes provide abstracts of current nursing research studies and explain the implications for your daily practice.

Nursing Care Plans feature a format that helps you understand the process of assessment, the relationship between assessment findings and nursing diagnoses, the identification of goals and outcomes, the selection of interventions, and the process for evaluating care.

BOX 13-4 NURSING CARE PLAN

Acute Pain

Assessment

Ms. Devine is a 52-year-old woman who was injured in a fall two months ago that caused rupture of a lumbar disc. She is scheduled for a lumbar laminectomy this afternoon. Ms. Devine is the office manager for a realty business she runs with her husband. She was

not able to work regularly over the first month after the injury. She has sciatic pain that is sharp and burning, radiating down from her right hip to her right foot. The pain worsens when she sits. Her vital signs are as follows: temperature 37.3°C; blood pressure, 138/82 mm Hg; pulse, 84 beats per minute; and respirations, 24 breaths per minute.

Assessment Activities

Observe client's body movements.

Findings and Defining Characteristics*

Client limps slightly with right leg. Turns in bed slowly.

Observe client's facial expression.

Client grimaces when she attempts to sit down.

Ask client to rate pain at its worst.

Client rates pain on a scale of 0 to 10 at an 8 or 9 at its worst.

*Defining characteristics are in italic type.

Nursing Diagnosis: Acute pain related to pressure on spinal nerves

Planning

Goal (Nursing Outcomes Classification)¹

Pain Control

Client will achieve improved pain control before surgery.

Expected Outcomes

Knowledge of Treatment

Client's self-report of pain will

Client's facial expressions reveal

¹Outcomes classification labels from Moorhead, S., Johnson, M., Maas, M., & Swanson, E. (Eds.). (4th ed.) St. Louis, MO: Mosby.

Interventions (Nursing Interventions Classification)¹

Analgesic Administration

Set positive expectations regarding effectiveness of analgesics.

Rationale

Optimizes client's response to medication (Bulechek et al., 2008).

Give analgesic 30 minutes before turning or positioning client and before pain increases in severity.

Medication will exert peak effect when client increase movement.

Pain Management

Reduce environmental factors in client's room (e.g., noise, lighting, temperature extremes).

Pleasurable sensory stimuli reduce pain perception.

Offer client information about any procedures and efforts at reducing discomfort.

Information satisfies client's interests and enables client to evaluate and communicate pain (McCaffery & Pasero, 1999).

Progressive Muscle Relaxation

Direct client through progressive muscle relaxation exercise. Coach client through exercise.

Relaxation techniques enable self-control when pain develops, reversing the cognitive and affective-motivational component of pain perception.

¹Intervention classification labels from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Mosby.

Evaluation

Nursing Actions

Ask client to report severity of pain 30 minutes after analgesic administration.

Client Response and Finding

Ms. Devine reports pain at a level 5 on a scale of 0 to 10.

Achievement of Outcome

Pain is reduced, necessitates further nonpharmacological intervention to achieve outcome.

Observe client's facial expressions.

Ms. Devine is observed to have a relaxed facial expression.

Client's level of comfort is improving.

Evaluation explains how to evaluate and determine whether the outcomes have been achieved.

Rationales for each of the interventions in the care plans help you to understand why a specific step or set of steps is performed.

2008). Extra weight, particularly in obese and moderately obese individuals, is believed to increase intrapelvic pressure; in one study, women who lost an average of 15 kg experienced a 51% reduction in incontinent episodes (Hunnskaar, 2008).

Caffeine contributes to urinary incontinence as it has a diuretic action and irritant effect (Cassel & Skelly, 2006). You can play an important role in educating, counselling, and supporting the patient to enable lifestyle modification that reduces the risk factors for incontinence.

Pelvic Floor Muscle Exercises. The pelvic floor musculature (PFM) spans the opening in the bony pelvis and combines with connective tissue to provide structural support for the pelvic organs. A well-toned PFM maintains the bladder neck in position to ensure that any increase in intra-abdominal pressure, as occurs with coughing, is transmitted not only to the bladder but also to the bladder neck to maintain closure. Contraction of the PFM results in urethral compression as the urethra is pulled forward toward the symphysis pubis (Ashton-Miller & Delancey, 2007). Weakened PFMs can result from muscle wasting caused by prolonged immobility, frequent straining in association with urinary or fecal elimination, stretching of muscles during childbirth, menopausal muscle atrophy, or traumatic damage.

Pelvic floor muscle exercises (PFMEs), also known as **Kegel exercises**, improve the strength of PFMs through hypertrophy and recruitment of additional muscle fibres associated with repetitive contractions (Ashton-Miller & Delancey, 2007). These exercises have demonstrated effectiveness in treating stress incontinence, overactive bladders, and mixed causes of urinary incontinence (Dolman, 2007). Patients begin these exercises during voiding to learn the technique: if they are able to slow the urinary stream, they are contracting the proper muscles. The exercises are then practised at nonvoiding times (Box 43-13). Patients should be alert and motivated to perform the exercises. They also should be aware that it may take 12 to 16 weeks to notice appreciable change, but that maintaining the exercises is important to obtain a positive outcome.

Bladder Training. The goal of bladder training is to increase gradually the interval between voids and to decrease voiding frequency (Eustice, 2007). The overall purpose is to restore a normal pattern of voiding. For bladder training to be successful, patients must be alert, motivated, and physically able to follow a training program. The program includes education, scheduled voiding, and positive reinforcement.

The first step in bladder training is establishing a baseline. The patient or caregiver completes a urinary diary to assess maximum voiding intervals. It is not uncommon for the patient with frequency or an overactive bladder to void small amounts hourly or more often. An initial training schedule for such a patient might involve a voiding schedule of every 75 minutes while awake, increasing every one to three weeks by 15-minute increments toward a three-hour schedule. The rate of incremental changes will depend on the patient's progress and on his or her ability to adhere to a rigid schedule. Urge-suppression techniques, such as counting backward from 100 when the urge to void is felt and performing pelvic floor muscle contractions, are helpful. You must be aware that the patient who has experienced an episode of incontinence in public will be particularly hesitant to deter voiding for even brief periods.

Habit Retraining and Prompted Voiding. Habit

Evidence-Informed Practice Guideline

boxes provide examples of recent state-of-the-science guidelines for nursing practice.

BOX 43-13 PATIENT TEACHING

Pelvic Floor Muscle Exercises (Kegels)

Objectives

The patient who is cognitively alert and motivated will achieve continence or experience fewer episodes of incontinence as a result of increased pelvic floor muscle tone and strength.

Teaching Strategies

- Explain the method used to identify proper muscle contraction: female patient sits on the toilet with knees apart and tightens muscles to stop the flow of urine; a male patient tries to stop the flow of urine midstream.
- After muscle is identified, instruct the patient to lie down with knees bent and apart, or to sit.
- Instruct the patient to contract the pelvic floor muscle gradually and hold the contraction for 3 to 10 seconds without tensing the muscles of the legs, buttocks, back, or abdomen. Remind the patient to breathe during the exercise.
- Instruct the patient to relax the muscle gradually for an equal time period between each contraction.
- The patient should repeat this exercise at least two or three times, and work up to 10 repetitions as it becomes easier. The patient should do this exercise two or three times a day, or as often as possible.
- Explain that within the first week of exercises, the patient and nurse can assess whether proper muscle contraction is occurring by patient placing two fingers in the vagina (or, for men, one finger in rectum) while contracting the pelvic floor muscle. The patient should feel tightening in the vagina or anus during the contraction.
- Teach the patient and the caregiver to keep a 24- to 72-hour urinary diary to identify changes in patterns of urinary elimination.

BOX 43-14 EVIDENCE-INFORMED PRACTICE GUIDELINE

Prompted Voiding for People With Urinary Incontinence

- Approach the patient at scheduled prompted voiding times.
- Wait five seconds for the patient to initiate a request to toilet.
- Ask the patient if he or she is wet or dry.
- Physically assess the patient to determine continence status.
- Provide positive feedback if the patient is dry.
- Prompt the patient to toilet.
- Offer assistance with toileting.
- Provide feedback.
- Inform the patient of the next scheduled prompted voiding session.
- Encourage the patient to self-initiate requests to toilet.
- Record the result of the prompted voiding session.

Source: Adapted from Wyman, J. (2008). Prompted voiding. In B. Ackley, B. Swan, G. Ludwig, & S. Tucker (Eds.), *Evidence-based nursing care guidelines: Medical-surgical interventions* (pp. 696-698). St Louis, MO: Mosby.

self-catheterization. In general, the goal is to have patients perform self-catheterization every six to eight hours, but the schedule should be individualized.

Evaluation

Patient Care

The patient is the best source of evaluation of outcomes and responses to nursing care (Figure 43-18). However, you will also evaluate the effectiveness of nursing interventions through comparisons with baseline data. You should evaluate for changes in the patient's voiding pattern, the presence of urinary tract alteration, and the patient's physical condition. Actual outcomes are compared with expected outcomes to determine the patient's health status. Continuous evaluation allows you to determine whether new or revised therapies are required or if any new nursing diagnoses have developed.

Patient Expectations

If you have developed a trust relationship with the patient, indications of the patient's degree of satisfaction with his or her care will be evident. The patient may smile or nod in appreciation. However, you need to confirm whether the patient's expectations have been met to full satisfaction. You may need to ask specifically about the patient's degree of urinary control and comfort. If simply asked, "How are you feeling today?" the patient may reply with a noncommittal "Okay." However, you need specific information about how well an intervention has met the patient's need in order to continue or to revise the care plan. You can also assist the patient in redefining unrealistic expectations when impairment in function is not likely to be altered as completely as he or she might like.

KEY CONCEPTS

- The act of micturition, or voiding, is influenced by voluntary control from higher brain centres and involuntary control from the spinal cord.

Patient (Client) Teaching boxes highlight what and how to teach patients and how to evaluate learning.

Figure 43-18 Critical thinking model for urinary elimination evaluation.

- Symptoms common to urinary disturbances include urgency, frequency, dysuria, polyuria, oliguria, and difficulty in starting the urinary stream.
- When collected properly, a clean-voided urine specimen does not contain bacteria from the urethral meatus.
- Methods of promoting the micturition reflex assist patients in sensing the urge to urinate and in controlling urethral sphincter relaxation.
- An increased fluid intake results in increased diluted urine formation that reduces the risk of urinary tract infections.
- An in-dwelling urinary catheter remains in the bladder for an extended period, making the risk of infection greater than with intermittent catheterization.
- Catheter irrigation is necessary when the catheter becomes occluded with sediment or blood clots.
- A catheter drainage system should be a closed system positioned to allow free drainage of urine by gravity.
- Incontinence is classified as transient, urge, stress, mixed, functional, overflow, reflex, or total. Each type has specific nursing interventions.
- Specific guidelines for catheter selection should be followed so that the catheter does not cause harm.

assessment should result in the formulation of nursing diagnoses appropriate for alterations in urinary elimination. You should be alert to individual needs related to normal aging that predispose older adults to certain elimination problems (Box 43-2).

* BOX 43-2 FOCUS ON OLDER ADULTS

- Physiological changes in the lower urinary tract occur in continent as well as incontinent older adults.
- Dilute urine discourages bacterial growth; therefore, older adults should be encouraged to increase their fluid intake to at least six glasses a day, unless medically contraindicated (Dubeau et al., 2009).
- Fluids that promote an acidic urine (e.g., cranberry juice) should be made available as part of the patient's fluid intake because an acidic urine also helps to inhibit bacterial growth and may prevent UTIs (Nguyen, 2008).
- Restriction of fluids two hours before sleep, combined with elevating the legs to allow for venous return and bladder emptying before bedtime (leg elevation for at least one hour) may decrease the incidence of nocturia (Dubeau et al., 2009).
- In-dwelling catheters should not be used routinely in older adults unless other options have been tried. The risk of infection increases dramatically for catheterized patients (Duthani-Mehta, 2007).
- Treating asymptomatic bacteriuria in older adults is not recommended.
- Incontinence is not a normal part of aging, and efforts should be made to assess incontinence and provide interventions to promote return to continence.

Health History

The nursing health history includes a review of the patient's urinary elimination patterns and symptoms of urinary alterations and an assessment of factors that may affect the ability to urinate normally.

Pattern of Urination. Ask the patient about usual daily voiding patterns and any recent changes. Information about voiding symptoms such as hesitancy (Table 43-1) and the overall pattern of urination, including average time between voids and episodes of urgency and incontinence, is important to a nursing assessment and establishes a baseline for comparison.

A **urinary diary** is an important diagnostic tool (Figure 43-7), particularly because many adults are not aware of how often they void throughout the day. A diary is kept by the patient or the caregiver; it records approximate times of urination, times of leakage and estimates of the amount lost (dribbled, wet pad, wet clothing), and types and amount of fluids ingested. Measuring two or more voids (not including the first void of the morning) will provide useful information about the volume of urine that a patient generally stores. Recording factors that precipitated urination or leakage, such as a strong urge or a cough, is particularly helpful. The number of pad changes per day is also useful information. A three-day (72-hour) voiding diary helps in evaluating lifestyle habits (e.g., fluid intake) in relation to the voiding pattern and symptoms (Ermer-Selton, 2006).

Factors Affecting Urination. It is important to summarize the factors associated with the patient's medical history, surgical history, and current environment that may affect urination. Medical history includes disease conditions that can affect elimination, such as multiple sclerosis, spinal cord injury, stroke, and diabetes. Another factor to consider is the patient's

► TABLE 43-1 Common Symptoms of Urinary Alterations

Symptom	Description	Common Cause
Incontinence	Involuntary loss of urine	Multifactorial
Urgency	Sudden and compelling urge to void that cannot be postponed	Overactive bladder
Dysuria	Painful or difficult urination	Bladder infection
Frequency	Voiding more than eight times in 24 hours	Increased bladder activity
Hesitancy	Difficulty initiating urination	Hypotension
Polyuria	Voiding large amounts of urine	Excessive fluid intake
Oliguria	Diminished urinary output relative to intake (usually 400 mL/24 hours)	Dehydration
Nocturia	Getting up at night to void	Excessive fluid intake
Dribbling	Leakage of urine despite voluntary control of urination	Stress incontinence
Hematuria	Blood in the urine	Nephritis
Retention	Accumulation of urine in the bladder, with inability of bladder to empty fully	Urethral obstruction
Elevated postvoid residual urine	Elevated volume of urine remaining after voiding (>100 mL)	Neurogenic bladder

1078 Unit VIII Basic Physiological Needs

parental knowledge of health, both of which relate to income status (Riediger et al., 2007). At the same time, lower socioeconomic status is associated with physical inactivity in Canadian adolescents (Janseen et al., 2006).

Approximately 3.7 million (15%) Canadians rely on food banks that are unable to supply recommended amounts of fresh fruits, vegetables, dairy products, and meats and alternatives (Irwin et al., 2007). The problem is worsened when children cannot access nutritional programs at schools (Henry et al., 2003). In Atlantic Canada, low-income lone mothers and their older children have poor diet quality (Glanville & McIntyre, 2006).

Although mandatory fortification of staple foods with micronutrients has helped to reduce income-related disparities (Ricciotti & Tarasuk, 2006), other interventions are also needed to counter the threat to good nutrition and health from lack of purchasing power at individual and collective levels. For those on limited budgets, food preparation can be modified for substances that need to be used sparingly; for example, bean or cheese dishes can often replace meat. Menu planning a week in advance helps patients comply with a specific diet, eat nutritiously, and stay within their budget. A nurse or dietitian may check menus for content. Often, simple tips can help, such as baking rather than frying to reduce fat intake, using lemon juice or spices to add flavour to low-sodium diets, and

Focus on Older Adults boxes prepare you to address the special needs of older adults.

avoiding grocery shopping when hungry because it can lead to spontaneous purchases of foods not included in meal plans. Strategies to help financially disadvantaged groups improve their nutrition include collective kitchens and gardens (Engler-Stringer & Berenbaum, 2005), coalitions with community-based organizations, antipoverty advocacy, and political commitment to policies of full employment (Power, 2005). Also important are public-awareness forums (Chapman, 2006) and a rights-based approach to food security at federal and provincial levels (Rideout et al., 2007) with support to families that have inadequate resources to meet their daily nutritional needs (Kurtz Landy, 2007). See Box 42-8 for an example of an innovative program that aims to increase food security for individuals, families, and communities.

safety alert Food safety is also an important public health issue. Food-borne illnesses can occur from poor hygiene practices and improper food storage or preparation. Nurses should educate patients about reducing the risks of food-borne illnesses (Table 42-7 and Box 42-9).

Acute Care

Many factors influence nutritional intake in acute care settings. Ill or debilitated patients often have loss of appetite (**anorexia**). The ketosis that accompanies starvation can further suppress

Focus on Primary Health Care boxes draw attention to principles of primary health care and their application.

* BOX 42-8 FOCUS ON PRIMARY HEALTH CARE

Case Study

Foodshare (Toronto) is a nonprofit community organization that promotes "good healthy food for all" while reducing costs to the health care system. Since 1985, Foodshare has worked with communities to improve nonstigmatizing access to affordable, nutritious, sustainably produced food through innovative programs, food markets, and policy recommendations. Food security is facilitated through the creation and distribution of resources, training workshops, networks, and coalitions. Food issues are addressed from the growing and processing of food to its distribution, purchasing, cooking, and consumption. The Foodshare programs try to rebuild food skills that are quickly being lost in Canadian society as people abandon the family meal tradition and turn increasingly to fast foods and eating on the run. Foodshare partners (e.g., the Government of Ontario, Public Health Services, community clinics and shelters, school boards, and the Volunteer Action Online program), professionals, teachers, parents, and volunteers work together to promote a locally sourced, grow-your-own-food lifestyle in various ways:

- **FoodLink Hotline:** Telephone referral 416-392-6655 available Monday to Friday 10 A.M. to 4 P.M. for those seeking information on food programs.
- **Community gardening programs:** Information, training (e.g., composting workshops), and resources provided to individuals and groups in preparing gardens and harvesting the produce.
- **Incubator Kitchen:** A fully equipped kitchen that provides groups without access to a commercial kitchen the opportunity to come together to plan and prepare low-cost nutritious meals in bulk.
- **The Good Food Box:** This food distribution system provides fresh fruit and vegetables at wholesale prices to over 200 community drop-off sites across the City of Toronto reaching 12,000 people. Individuals and families who are part of neighbourhood-based groups pay for and order food in advance. The program workers purchase foods in bulk to support local farmers; volunteers and

staff pack and deliver the food boxes to the drop-off sites. All boxes are accompanied by a newsletter offering nutrition information and economical food preparation tips. The "Reach for 5" basket, geared to seniors, contains prepared, cut-up fruit and vegetables.

- **Power Soups and Power Meals:** Foodshare makes dense soups, meals, and nutrition/training workshops available at a heavily subsidized price to Toronto shelters and drop-ins serving the homeless, which enables the underprivileged to have access to a wholesome meal.
- **Baby Nutrition:** Food-related activities for families with infants and preschoolers include workshops on making homemade baby food from fresh affordable food and cooking with kids.
- **Partners for Student Nutrition:** Foodshare works with Toronto Public Health and other community agencies to sponsor 300 student nutrition programs in Toronto.
- **Focus on Food:** A training program for marginalized youth focusing on community service and developing cooking, gardening, and nutrition skills.
- **Field to Table Wholesale Produce:** A community development project that makes fresh fruit and vegetables available and affordable to schools (e.g., the "Salad Bar" project) in order to promote increased consumption of fresh, nutritious foods among children.
- **Partnership with Canadian Mental Health Association:** Individuals living with mental health challenges earn minimum wage and gain valuable job skills producing sprouts and seedlings for sale.
- **Online food security resource centre:** An interactive library of electronic and print newsletters, food program manuals, community resource sites such as sustainable agriculture and anti-poverty issues with links to key Web sites, listservs, e-bulletins, and archived, current, and upcoming workshops.

SKILL 45-1 Moving and Positioning Patients in Bed

Delegation Considerations

The skills of moving and positioning patients in bed can be delegated to unregulated care providers (UCPs). The nurse is responsible for assessing the patient's level of comfort and for any potential hazards. It is important to instruct the UCP on any limitations affecting movement and positioning of the patient in bed.

Procedure

STEPS

1. Assess patient's body alignment and comfort level while patient is lying down.
2. Assess for risk factors that may contribute to complications of immobility:
 - A. Paralysis: Hemiparesis resulting from cerebrovascular accident; decreased sensation
 - B. Impaired mobility: Traction or arthritis or other contributing disease processes
 - C. Impaired circulation
 - D. Age: Very young, older adults
 - E. Level of consciousness and mental status
 - F. Assess condition of patient's skin.
3. Assess patient's physical ability to help with moving and positioning:
 - A. Age
 - B. Level of consciousness and mental status
 - C. Disease process
 - D. Strength, coordination
 - E. ROM
4. Assess physician's orders. Clarify whether any positions are contraindicated because of the patient's condition (e.g., spinal cord injury, respiratory difficulties, certain neurological condition, presence of incisions, drain, or tubing).
5. Perform hand hygiene.
6. Assess for the presence of tubes, incisions, and equipment (e.g., traction).
7. Assess the ability and motivation of the patient, family members, and primary caregiver to participate in moving and positioning the patient in bed in anticipation of discharge to home.
8. Raise level of bed to a comfortable working height, and get extra help if needed.
9. Perform hand hygiene.
10. Explain procedure to patient.
11. Position patient flat in bed if this is tolerated.

Critical Decision Point: Before flattening the bed, account for all tubes in the mattress or bed frame as bed is lowered.

Equipment

- Pillows
- Drawsheet or friction-reducing device
- Positioning devices as required (e.g., trochanter roll, extra pillows, hand rolls)

RATIONALE

- Provides baseline data for later comparisons. Determines ways to improve position and alignment.
- Increased risk factors require patient to be repositioned more frequently.
- Paralysis impairs movement and causes muscle-tone changes; sensation can be affected. Because of difficulty in moving and poor awareness of the involved body part, the patient is unable to protect and position the affected body part.
- Traction or arthritic changes of affected extremity result in decreased range of motion (ROM).
- Decreased circulation predisposes the patient to pressure sores.
- Premature and young infants require frequent turning because their skin is fragile. Normal physiological changes associated with aging predispose older adults to greater risks for developing complications of immobility.
- Patients who are comatose or semicomatose are unable to convey areas of skin pressure, increasing the risk for skin breakdown.
- Provides a baseline to determine effects of positioning.
- Enables nurse to use patient's mobility and strength. Determines need for additional help. Ensures patient's and nurse's safety.
- Older adult patients may move more slowly and with less strength.
- Determines need for special aids or devices.
- Patients with altered levels of consciousness may not understand

Nursing Skills are presented in a clear, two-column format that includes Steps and Rationales to help you learn how and why a skill is performed.

Video icons indicate video clips associated with specific skills that are available on the free *Evolve Student Learning Resources*.

Delegation Considerations guide you in delegating tasks to assistive personnel.

Critical Decision Points alert you to critical steps within a skill to ensure safe and effective client care.

Clear, close-up **photos and illustrations** show you how to perform important nursing techniques.

Recording and Reporting sections provide guidelines for what to chart and report with each skill.

Home Care Considerations explain how to adapt skills for the home setting.

SKILL 45-1 Moving and Positioning Patients in Bed—cont'd

- (3) Position two nurses on side of bed to which the patient will be turned. Position third nurse on the other side of bed (see Step 12K[3] illustration).
- (4) Fanfold or roll the drawsheet or pull sheet.
- (5) Move the patient as one unit in a smooth, continuous motion on the count of 3 (see Step 12K[5] illustration).

Step 12K(3) Position nurses on each side of patient.

- (6) The nurse on the opposite side of the bed places pillows along the length of the patient (see Step 12K[6] illustration).
- (7) Gently lean the patient as a unit back toward the pillows for support (see Step 12K[7] illustration).

Step 12K(6) Place pillows along patient's back for support.

13. Perform hand hygiene.
14. Evaluate patient's level of comfort and ability to assist in position change.
15. After each position change, evaluate patient's body alignment and presence of any pressure areas. Observe for areas of erythema or breakdown involving skin.

Unexpected Outcomes

Joint contractures

Skin erythema and breakdown

Patient avoids moving

Recording and Reporting

- Record procedure and observations (e.g., condition of skin, joint movement, patient's ability to assist with positioning).
- Report observations at change of shift and document in nurses' notes.

Home Care Considerations

- Teach the family about the importance of body mechanics for themselves and the patient.
- Teach the patient and family about the signs of skin breakdown and the importance of safety during positioning patients with decreased sensation or mobility.

- Distributes weight equally among nurses.

- Provides strong handles to grip the drawsheet or pull sheet without slipping.
- Maintains proper alignment by moving all body parts at the same time, preventing tension or twisting of the spinal column.

Step 12K(5) Move patient as a unit, maintaining proper alignment.

- Pillows keep the patient aligned.

- Ensures continued straight alignment of spinal column, preventing injury.

Step 12K(7) Gently lean patient as a unit against pillows.

- Reduces transmission of microorganisms.
- Patients with reduced activity tolerance and increased levels of pain may find position changes very tiring and will need post-position change interventions to restore their level of comfort.
- Prompt identification of poor alignment reduces risks to the patient's skin and musculoskeletal systems.

Related Interventions

- Improper positioning results in shortening of muscles.
- Frequency of repositioning is inadequate.
- Place turning schedule above patient's bed.
- Frequency of repositioning is inadequate.
- Place turning schedule above patient's bed.

benefits for patients with acute respiratory distress syndrome and acute lung injury (Marklew, 2006).

Assess for and correct any of the following potential trouble points for patients in the prone position (see Skill 45-1 for preventive measures):

- Neck hyperextension
- Hyperextension of the lumbar spine
- Plantar flexion of the ankles
- Unprotected pressure points at the chin, elbows, hips, knees, and toes

Side-Lying Position. In the side-lying (or lateral) position, the patient is resting on the side with the major portion of body weight on the dependent hip and shoulder. A 30-degree lateral position is recommended for patients at risk for pressure ulcers (see Chapter 46). Trunk alignment should be the same as in standing. For example, the structural curves of the spine should be maintained, the head should be supported in line with the midline of the trunk, and rotation of the spine should be avoided. The following trouble points are common in the side-lying position (see Skill 45-1 for preventive measures):

- Lateral flexion of the neck
- Spinal curves out of normal alignment
- Shoulder and hip joints internally rotated, adducted, or unsupported
- Lack of support for the feet
- Lack of protection for pressure points at the ear, shoulder, anterior iliac spine, trochanter, and ankles
- Excessive lateral flexion of the spine if the patient has large hips and a pillow is not placed superior to the hips at the waist

Sims' Position. Sims' position differs from the lateral position in the distribution of the patient's weight. In Sims' position, the weight is placed on the anterior ilium, humerus, and clavicle. Trouble points common in Sims' position include the following (see Skill 45-1 for preventive measures):

- Lateral flexion of the neck
- Internal rotation, adduction, or lack of support to the shoulders and hips
- Lack of support for the feet
- Lack of protection for pressure points at the ilium, humerus, clavicle, knees, and ankles

Transfer Techniques. Nurses often provide care for patients who must be assisted to change positions, who must be moved up in bed, or who must be transferred from a bed to a chair or from a bed to a stretcher. Use of proper body mechanics will enable you to position, move, or transfer patients safely and also protect you from injury to the musculoskeletal system (see Chapter 35). Although many transfer techniques are used, the following general guidelines should be followed in any transfer procedure:

- Raise the side rail on the side of the bed opposite you to prevent the patient from falling out of bed.
- Elevate the level of the bed to a comfortable working height.
- Assess the patient's mobility and strength to determine what assistance the patient can offer during transfer.
- Determine the need for assistance from other care providers or mechanical lifts.
- Explain the procedure to the patient and describe what is expected of the patient.
- Assess for correct body alignment and pressure areas after each transfer.

safety alert Recognition of your own personal strengths and limits is crucial. Moving a patient who is completely immobilized alone is dangerous and not allowed in many agencies. If you are attempting transfer or moving techniques for the first time, you should request help to reduce the risk of injury to yourself and to the patient.

Moving Patients. Patients require various levels of assistance to move up in bed, move to the side-lying position, or sit up at the side of the bed. For example, a young, healthy woman may need only a little support as she sits at the side of the bed for the first time after childbirth, whereas an older person may need help from one or more nurses to do the same task one day after abdominal surgery.

Always enlist the patient's help to the fullest extent possible. To determine what the patient is able to do alone and how many people are needed to help move the patient in bed, you need to assess the patient to determine whether the illness contradicts exertion (e.g., cardiovascular disease).

Next, determine whether the patient comprehends what is expected. For example, a patient recently medicated for postoperative pain may be too lethargic to understand instruction. To ensure safety, two nurses would be needed to move the patient in bed. You must then determine the comfort level of the patient and evaluate personal strength and knowledge of the procedure.

Finally, determine whether the patient is too heavy or immobile for you to complete the procedure alone (see Skill 45-1). If in doubt, always request assistance from another person. Collaborate with the physiotherapist, occupational therapist, and physician to plan for mobilizing the bariatric patient (Box 45-9). Use of mechanical transfer devices may be warranted (Figure 45-18), and agency lifting and transferring policies must be followed (Worksafe BC, 2006).

Assessment criteria and tools have been developed to help you gather data and to assess and plan for the safe transfer of patients. An example of a patient mobility assessment form is shown in Table 45-4.

Transferring a Patient from a Bed to a Chair. Transfer of a patient from a bed to a chair by one nurse requires assistance from the patient and should not be attempted with a patient who cannot help (Skill 45-2). Explain the procedure to the patient before the transfer. Moving obstacles out of the way also prepares the environment. The chair is placed next to the bed with the chair back in the same plane as the head of the bed. Placement of the chair allows you to pivot with the patient and to transfer the patient's weight in a controlled manner.

A safe transfer is the first priority. If you are doubtful about personal strength or the patient's ability to help, you should request assistance. A transfer belt should be used with all patients being transferred for the first time and thereafter as deemed necessary. Use of a transfer belt (called a gait belt when used for walking with a patient) helps prevent caregiver back injuries and aids in the safe transfer of the patient. The belt encircles the patient's waist and has handles attached for the nurse to hold. It is applied over the patient's clothing, never over bare skin. The belt is tightened so that it is snug but does not cause discomfort or impair breathing, and the buckle is placed off-centre in the front or in the back. The buckle should not be over the spine.

The patient should sit and dangle the feet at the side of the bed for a minute before standing. The patient should then stand at the side of the bed for another minute so that he or

over the past several decades, many nurses became dissatisfied with a purely medical approach to care, partly because people realized that scientific research could not answer all the existential questions raised by patients (McSherry, 2001). Nurses felt a spiritual gap in the profession and began to find ways to articulate and incorporate spirituality into practice and research. Spirituality was conceptualized as broader than any particular religion or culture. Between 1980 and 2000, renewed interest in spirituality was reflected by an increase in nursing literature on spirituality, as well as a growing interest in parish nursing as a way for faith communities in Canada to reclaim their healing mission (Miller, 2004; Olson et al., 1998).

Canadian nursing scholarship has made important contributions by emphasizing the relationship between spirituality, religion, health, and culture (Kulig et al., 2004; Labun & Emblen, 2007; Pesut et al., 2008). For example, in their study of spirituality and health in Punjabi Sikh living in British Columbia, Labun and Emblen (2007) stated that an understanding of the interplay of spirituality, religion, and health informs culturally competent care. Just as Canadian nurses must understand cultural influences in health and illness, they must also recognize the need for sensitive, safe, and ethical nursing care in which patients' spiritual needs and resources are recognized and supported (Box 27-1). Because Canada is a pluralistic society in which diversity is valued, Canadian nurses must recognize how diverse views influence the way patients (and nurses) view spirituality (Pesut, 2006; 2009).

Spirituality and Health: Empirical Evidence

Spiritual health has been defined as "a connectedness with self, others, and the sacred that transcends and empowers the self" (Como, 2007, p. 226). Spiritual needs may increase as health declines (Bruce et al., 2011; Carson & Koenig, 2008; McSherry, 2006). There is increasing evidence that spirituality

Safety Alerts indicate techniques you can use to ensure patient and nurse safety.

Cultural Aspects of Care boxes prepare you to care for patients of diverse populations and suggest actions needed to meet different cultural needs and preferences.

BOX 27-1 CULTURAL ASPECTS OF CARE

In caring for patients from different cultures, it is important that you take into account their cultural understandings of spirituality and religion. You must determine what is important in their lives and what provides them with inner strength and meaning. Patients are often attempting to find meaning in the changing circumstances of their health and illness but that meaning will differ depending on their values and beliefs. For example, Shih et al. (2009) explored the spiritual needs of older Taiwanese patients with terminal cancer using participant observation and in-depth interviews. They suggested that caring for the body and transcending worldly being were common patterns and emphasized, among other things, the important role of the funeral ceremony in purifying the soul and contributing positively to the afterlife. Similarly, Mok, Wong, and Wong (2010) explored through interviews the meaning of spirituality and spiritual care among Hong Kong Chinese terminally ill. An important finding from this study was that all participants had difficulty understanding and expressing spirituality. Further, they did not expect spiritual care from nurses but desired quality interpersonal care. Reimer-Kirkham (2009) explored the negotiation of religious and spiritual plurality in health care encounters and used the example of Sikh patients to highlight how lived religion is a moral code that informs all of life and has important implications for ethical nursing care.

Implications for Practice

- Explore the spirituality of patients within the contexts and meanings of their own cultures. Spirituality may not be the language that is most familiar to them. It is always appropriate to explore the meaning of health and how patients achieve balance, stability, peace, or comfort in their lives.
- Offer a universal and holistic approach to patients by demonstrating caring and by using therapeutic communication techniques.
- Promote an environment during assessment in which human rights, values, customs, and spiritual beliefs are respected.
- Include appropriate spiritual or religious care providers.
- Avoid the use of language that alienates patients or discriminates between different religions (e.g., asking whether the patient wants someone from his or her "faith community" to visit, rather than "temple," "church," or "synagogue").
- Understand that different cultures and religions have ethical codes that are an important part of ethical nursing care.

has the potential to mobilize personal capacities, illness-coping strategies, and positive health behaviours (Como, 2007; Krok, 2008; Lawler-Row & Elliott, 2009; Levin, 2010; Vespa et al., 2011; Whelan-Gales et al., 2009). For example, research involving 263 patients with cancer found that those who reported healthy inner spirituality, spiritual coping, and spiritual well-being were less likely to experience depression and intrapersonal/interpersonal conflicts (Vespa et al., 2011). Positive spiritual and religious coping has also been linked to a

factors during an admission nursing assessment. Many interventions reduce the risk of thrombus formation in the patients who are immobilized. Leg exercises, encouragement of fluids, position changes, and teaching of such preventive measures should begin when the patient becomes immobile. Preoperative patients should be given this information before surgery (see Chapter 48). Other interventions such as intermittent pneumatic compression (IPC) and sequential compression devices (SCDs) require a physician's order. Maintenance and administration of prophylaxis is a nursing role, and nurses can determine when the patient is fully mobile postoperatively, decreasing the continued risk for DVT.

Medications also require a physician's order. Subcutaneous heparin and low-molecular-weight heparin (LMWH), such as tinzaparin, enoxaparin, and dalteparin, are the most widely used drugs in the prophylaxis of DVT. The recent approval of rivaroxaban and dabigatran, in addition to the long-standing availability of warfarin, means more oral options for DVT prophylaxis and anticoagulation therapy. Heparin is considered the gold standard for treatment because it has been well studied and validated. Common dosage for heparin therapy is 5000 units given subcutaneously every 12 hours until the patient is fully mobile or discharged (Geerts et al., 2008). Anticoagulants suppress clot formation and thus you must continually assess the patient for signs of bleeding, such as increased bruising, guaiac-positive stools, and bleeding gums. Although most patients receiving prophylactic doses of anticoagulants do not experience side effects, the risk of bleeding is present.

SCDs and IPCs consist of sleeves or stockings made of fabric or plastic that are wrapped around the leg and secured with Velcro (Box 45-7). The sleeves are then connected to a pump that alternately inflates and deflates the stocking around the leg. A typical cycle is inflation for 10 to 15 seconds and deflation for 45 to 60 seconds. Inflation pressures average 40 mm Hg. Use of SCDs or IPCs on the legs decreases venous stasis by increasing venous return through the deep veins of the legs. For optimal results, use of SCDs or IPCs is begun as soon as possible and maintained until the patient becomes fully ambulatory. Graduated compression stockings can help prevent DVT, but patients must receive the right size, and the SCD or IPC must be used correctly.

Elastic stockings (sometimes called *thromboembolic device (TED) hose* or thigh-high antiembolic stockings) also aid in maintaining external pressure on the muscles of the lower extremities and thus may promote venous return (Box 45-8). When considering applying elastic stockings, first assess the patient's suitability for wearing them. The stockings should not be applied if any local condition affects the leg (e.g., any skin lesion, gangrenous condition, or recent vein ligation) because application may compromise circulation. You will need to measure the patient's legs with a tape measure to determine proper stocking size. The stockings must be applied properly, and they must be removed and reapplied at least once per shift. Assess circulation at the toes to ensure that the hose are not too tight. In addition, the stockings should always be clean and dry; it may be useful for the patient to have two pairs.

Positioning techniques aid in reducing compression of the leg veins. Proper positioning used with other therapies (e.g., heparin or elastic stockings) aids in reducing the patient's risk of thrombus formation. When positioning patients, use caution to prevent pressure on the posterior knee and deep veins in the lower extremities. Patient teaching should include avoiding

Nursing Story boxes tell a real-life story concerning one or more topics in the chapter.

BOX 45-7 Procedural Guideline

Application of Sequential Compression Stockings

Delegation Considerations:

The skill of applying sequential compression stockings (SCSs) can be delegated to unregulated care providers (UCPs). The nurse is responsible for assessing circulation in the extremities; therefore, when application of the SCSs is delegated, it is important to instruct the UCP to do the following:

- Notify the nurse if the patient complains of pain in the leg
- Notify the nurse if discoloration develops in the extremities

Equipment:

Tape measure, sequential compression stockings, stockinette, hygiene supplies

Procedure:

1. Assess the patient for the need for sequential compression stockings.
 2. Obtain baseline assessment data about the status of circulation, pulse, and skin integrity on the patient's lower extremities before initiating application of sequential compression stockings.
 3. Measure the patient for proper-size stocking by measuring around the largest part of the patient's thigh. Review the manufacturer's directions regarding measuring for proper fit.
 4. Perform hand hygiene. Provide hygiene to lower extremities if needed.
 5. Place a protective stockinette over the patient's leg.
 6. Wrap the stocking around the leg, starting at the ankle, with the opening over the patella (see Step 6 illustration).
- A. Attach the stockings to the insufflator and verify that the intermittent pressure is between 35 and 45 mm Hg.

Procedural Guidelines provide streamlined, step-by-step instructions for performing basic skills.

Chapter 45 Mobility and Immobility 1199

BOX 45-1 NURSING STORY

Patient Rehabilitation

When Grace Lo was admitted to the inpatient rehabilitation unit, it was difficult for me to imagine her living independently in a condominium, driving her car, going out to lunch, shopping, or playing bridge with her friends. She looked so frail and tired, and she needed assistance with everything. Grace was a 66-year-old widow with a diagnosis of uterine cancer. After being diagnosed, Grace was started on chemotherapy to help shrink the size of the tumour before having surgery to remove it. She experienced side effects from the chemotherapy—anaemia and neutropenia. Unfortunately, she also developed recurrent pneumonia and had been immobilized in the intensive care and oncology units for over five weeks.

When Grace was admitted to the rehabilitation unit, she was significantly deconditioned. She had never enjoyed exercising and was feeling regret about not maintaining her physical fitness before her cancer diagnosis. Her ability to complete her chemotherapy treatments depended on her regaining her strength, endurance, mobility, and independence for her ADLs. Grace was very motivated to work with the rehabilitation team, but she was also afraid. What if she couldn't get strong enough to finish her chemotherapy?

At the beginning of rehabilitation, Grace needed assistance from two people for all her transfers. She had a Foley catheter in place, and she fatigued quickly with minimal exertion. Her respiratory status had been compromised by recurrent pneumonia and her past behaviour of cigarette smoking. The first goal was to increase her upper and lower extremity strength for transferring from the bed to a commode at the bedside. It took a coordinated interdisciplinary approach to work on Grace's pace at exercising and her ability to practise ADLs independently. Once Grace was able to safely transfer from the bed with a one-person, minimally assisted standing pivot transfer, the team was able to focus on the goal of urinary continence. Because she had been immobilized for an extended period of time, Grace often felt lightheaded and dizzy when sitting at the bedside before a transfer. These experiences contributed to her feelings of apprehension about falling and to a loss of confidence. It was important to raise the head of Grace's bed in increments before attempting transfers to minimize postural hypotension. After two weeks of exercising and practice, Grace was continent, using the bathroom in her room. However, she still had a long way to go.

Four months after she had been discharged from rehabilitation, I heard my name being called. A fit-looking woman was calling out to me—I barely recognized a radiant Grace. She had continued outpatient rehabilitation and was exercising regularly. Grace excitedly told me that she had finished her last cycle of chemotherapy. Her computerized tomography (CT) scan showed that the tumour in her uterus had decreased in size and she no longer needed surgery. Grace told me that while the diagnosis of cancer scared her, the experiences of being immobilized and dependent on others for all her ADLs had "terrified" her. Her story reminded me of the impact of immobility on all aspects of a person's life and of the importance of setting small, attainable goals in promoting independence and hope.

may result from a fecal impaction (accumulation of hardened feces). This finding is not normal diarrhea, but rather liquid stool passing around the area of impaction (see Chapter 44). Left untreated, fecal impaction can result in a mechanical bowel obstruction that may partially or completely occlude the intestinal lumen, blocking normal propulsion of liquid and gas. The resulting fluid in the intestine produces distension and increases intraluminal pressure. Over time, intestinal

function becomes depressed, dehydration occurs, absorption ceases, and fluid and electrolyte disturbances worsen.

Respiratory Changes. Regular aerobic exercise is known to enhance respiratory functioning. Conversely, lack of movement and exercise places patients at higher risk for respiratory complications. Patients who have recently had surgery or are immobile are at high risk for developing pulmonary complications. The most common respiratory complications are **atelectasis** (collapse of alveoli) and **hypostatic pneumonia** (inflammation of the lung from stasis or pooling of secretions). Both conditions decrease oxygenation, prolong recovery, and add to the patient's discomfort (Black & Hawks, 2009). In atelectasis, secretions block a bronchiole or a bronchus, and the distal lung tissue (alveoli) collapses as the existing air is absorbed, producing hypoventilation. The site of the blockage determines the extent of atelectasis. A lung lobe or even a whole lung may collapse. At some point in the development of these complications, the patient's ability to cough productively declines proportionately. Ultimately, the distribution of mucus in the bronchi increases, particularly when the patient is in the supine, prone, or lateral position. Mucus accumulates in the dependent regions of the airways. Because mucus is an excellent medium for bacterial growth, hypostatic pneumonia may result.

Cardiovascular Changes. The cardiovascular system is also affected by immobilization. The three major changes are orthostatic hypotension, increased cardiac workload, and thrombus formation.

Orthostatic hypotension is a drop of 20 mm Hg or more in systolic blood pressure and of 10 mm Hg in diastolic blood pressure within three minutes of when the patient rises from a lying or sitting position to a standing position (Medow et al., 2008). Decreased circulating fluid volume, pooling of blood in the lower extremities, and decreased autonomic response occur when a patient is immobile. These factors result in decreased venous return, followed by a decrease in cardiac output, which is reflected by a decline in blood pressure (McCance & Huether, 2010).

As the workload of the heart increases, its oxygen consumption does as well. The heart therefore works harder and less efficiently during periods of prolonged rest. As immobilization increases, cardiac output falls, further decreasing cardiac efficiency and increasing workload.

Patients are also at risk for thrombus formation. A **thrombus** is an accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, sometimes occluding the lumen of the vessel (Figure 45-1). Three factors contribute to venous thrombus formation: (1) loss of integrity of the vessel wall (e.g., injury), (2) abnormalities of blood flow (e.g., slow blood flow in calf veins associated with bed rest), and (3) alterations in blood constituents (e.g., a change in clotting factors or increased platelet activity). These three factors are sometimes referred to as **Virchow's triad** (McCance & Huether, 2010). A dislodged venous thrombus, called an **embolus**, may travel through the circulatory system to the lungs and impair circulation and oxygenation. Venous emboli that travel to the lungs are called **pulmonary emboli** and may be life-threatening. More than 90% of all pulmonary emboli begin in the legs or pelvis (Copstead-Kirkhorn & Banaski, 2011).

Musculoskeletal Changes. The effects of immobility on the musculoskeletal system can include temporary or permanent impairment. Restricted mobility may result in loss of

Preface to the Instructor

The future of nursing in Canada is promising. Dynamic change and ongoing development of the discipline point to the need for extensive and wide-ranging knowledge as the foundation for nursing practice. The nurses of tomorrow will continue to need to practise outstanding nursing and demonstrate its importance in maintaining and improving the health of Canadians within the context of global health challenges. Nursing practice will be characterized by (a) critical thinking, (b) patient/client advocacy, (c) excellence in clinical decision making, and (d) client/patient/community teaching within a broad spectrum of health services. Moreover, nursing practice will involve engaging in knowledge translation and leadership development and advocating for health policy change at the local, national, and global level. *Canadian Fundamentals of Nursing* is designed for students at all levels of undergraduate nursing programs. The text provides comprehensive coverage of fundamental nursing concepts, knowledge, research, and skills essential for nursing practice.

The fifth edition of *Canadian Fundamentals of Nursing* has been extensively revised and thoroughly edited to include the most current evidence, issues, and future directions for nursing in Canada. All 48 chapters have been written or revised so that they reflect Canadian standards, traditions, research, and practice. *Canadian Fundamentals of Nursing* includes content covering the entire scope of primary, secondary, tertiary, rehabilitation, and end-of-life care. The focus is on the central role of primary health care in all areas of nursing practice. Emphasis is also placed on evidence-informed practice in skills and care plans to foster understanding of how research findings should guide clinical decision making. The book includes concept maps that demonstrate the relationships among nursing assessment, diagnosis, planning, intervention, and evaluation. First-person accounts, in the form of Nursing Story boxes, of issues that have arisen in nursing practice are designed to engage the student's attention and encourage more detailed reading and understanding.

For this edition, we have chosen to use both the terms “evidence-based practice” and “evidence-informed practice.” *Evidence-based practice* refers to the use of research findings in everyday practice. *Evidence-informed practice* reflects the need to be context-sensitive and to consider use of the best available evidence in dealing with everyday circumstances based on clinical judgement.

This textbook is the result of the combined efforts of many expert professionals committed to excellence. Expert contributors from across Canada approached the revisions with enthusiasm and worked hard to ensure that the content is current and reflects the Canadian health care system, Canadian health and social organizations, and uniquely Canadian health care issues. Reviewers scrutinized the chapters and made many helpful suggestions. We appreciate the conscientiousness and enthusiasm of all these dedicated professionals.

Classic Features

- **Comprehensive** coverage and readability of all fundamental nursing content are provided.
- **Full-colour** text is used to enhance visual appeal and instructional value.
- **Primary health care and health promotion** issues are discussed throughout the text.
- **Focus on Primary Health Care** boxes highlight how the principles of primary health care can be applied to the topic of the

chapter; the context of each of these boxes pertains uniquely to Canadian health care.

- **Research Highlight** boxes are integrated throughout the text to provide current nursing research studies and explain the implications for daily nursing practice.
- **Patient/client education** is highlighted in boxes that list teaching objectives, strategies, and evaluation for clinical topics throughout the text.
- **Evidence-informed/based practice** is discussed throughout the text.
- **Evidence-Informed Practice Guidelines** boxes provide examples of recent state-of-the-science guidelines for nursing practice.
- **Nursing principles** specific to the older adult are addressed throughout the text.
- **Historical boxes** entitled **Milestones in Canadian History** provide information about nursing leaders and critical events in Canadian nursing history.
- **Nursing Story** boxes present first-person accounts of issues in relation to chapter content.
- **Nursing Care Plans** guide students on how to conduct an assessment and analyze the defining characteristics that indicate nursing diagnoses. The plans include Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) to familiarize students with this important nomenclature. The evaluation sections of the plans show students how to determine the expected outcomes and evaluate the results of care.
- **Concept Maps** demonstrate the relationship between nursing assessment, diagnosis, planning, intervention, and evaluation.
- **Procedural Guidelines** boxes provide step-by-step instructions and photos about how to perform basic skills.
- **Video icons** indicate video clips associated with specific skills that are available in the Evolve Student Learning Resources.
- **End-of-chapter review questions** assist students to critically review what they have learned. Answers and rationales are provided at the end of this textbook.
- The annotated **Recommended Web Sites** sections at the end of each chapter direct the student to current resources.
- The **Laboratory Values** appendix (Appendix B) is a concise, up-to-date source of current laboratory values for use in clinical practice.

New Features

- A new addition to **Global Health, Culture, and Diversity** (Chapter 9) is the evolving area of global health relative to social justice and global health inequities. To contribute to nurses' understanding of global health, key concepts of global citizenship, health equity, cultural safety, and diversity in relation to nursing practice are discussed.
- The revised **Community Health Nursing Practice** chapter (Chapter 4) now includes discussions of environmental health.
- The updated **Family Nursing** chapter (Chapter 19) includes consideration of family *in context*, or family nursing as relational inquiry. This extends the previous chapter's discussion of family *as context* and family *as client*. The new content emphasizes the need for nurses to explore the geopolitical, economic, and social influences that are at play when families encounter illness or other life transition challenges.

- A revised chapter on **Older Adulthood** (Chapter 24) includes the concepts of aging well and quality of life for older adults.
- Updates to the chapter on **Spiritual Health** (Chapter 27) include empirical evidence supporting the relationship of spirituality to health, and the chapter has been augmented with a section on the mind-body connection. Current evidence on spiritual care practices and what patients expect from nurses has been added. A theoretical shift is a focus away from nursing assessment towards understanding and reflecting on spirituality in a deeper sense for both nurses and patients. This shift is in keeping with the assumption that spirituality in practice is a co-created learning rather than one in which nurses take an expert role. A section on spirituality and ethics has been added to support students' considerations of the ethical dimensions of care in the area of spiritual health.
- An updated **Sensory Alterations** chapter (Chapter 47) includes the addition of a substantial amount of content on sensory changes, particularly content on vision and hearing. New Canadian resources have been added.
- **References** have been updated throughout to include Canadian research and practice standards, such as the best nursing practice guidelines of Health Canada, Statistics Canada, the Canadian Nurses Association (CNA), and the Registered Nurses Association of Ontario (RNAO). References have been organized by chapter and compiled at the end of the text.
- **Media Resources** listed at the beginning of each chapter detail the available Evolve resources.
- An updated **Practical Nursing in Canada** appendix (Appendix A) provides important information on this nursing role in Canada.

Learning Supplements for Students

- The **Evolve Student Resources** are available online at <http://evolve.elsevier.com/Canada/Potter/fundamentals/> and include the following valuable learning aids, organized by asset:
 - Animations
 - Audio Glossary
 - Calculation Tutorial
 - Examination Review Questions
 - Fluids and Electrolytes Tutorial
 - Interactive Learning Activities
 - Key Term Flashcards
 - Printable versions of Chapter Key Points
 - Skills Performance Checklists for each skill in the text
 - Video Clips highlighting common skills
- A thorough **Study Guide With Skills Performance Checklists** provides an ideal supplement to help students understand and apply the content of the text. Each chapter includes multiple sections:
 - **Preliminary Reading** includes a chapter assignment from the text.
 - **Comprehensive Understanding** provides a variety of activities to reinforce the topics and main ideas from the text.
 - **Review Questions** are multiple-choice, requiring students to provide rationales for their answers. Answers and rationales are provided in the answer key.
 - **Clinical chapters** include critical thinking models that expand the case study from the chapter's care plan. Students are asked to develop a step in the model on the basis of the actions of the nurse and patient in the scenario. This helps

students learn to apply both content learned and the critical thinking synthesis model.

- **Skills Performance Checklists** are included so that students can evaluate skill competency.
- The handy **Clinical Companion: Just the Facts** complements, rather than abbreviates, the textbook. Content is presented in tabular, list, and outline formats that equip your students with a concise, portable guide to all of the facts and figures they'll need to know in their early clinical experiences.
- **Virtual Clinical Excursions** is an exciting workbook and CD-ROM package that brings learning to life in a virtual hospital setting. The workbook guides students as they care for patients, providing ongoing challenges and learning opportunities. Each lesson in *Virtual Clinical Excursions* complements the textbook content and provides an environment for students to practice what they are learning. This CD/workbook is available separately or packaged at a special price with the textbook.

Teaching Supplements for Instructors

- The **Evolve Instructor Resources** (available online at <http://evolve.elsevier.com/Canada/Potter/fundamentals/>) are a comprehensive collection of the most important tools instructors need, including the following:
 - **TEACH for Nurses** ties together every chapter resource you need for the most effective class presentations, with sections dedicated to objectives, teaching focus, instructor chapter resources, answers to chapter questions, and an in-class case study discussion. Teaching strategies include content highlights, student activities, online activities, and large group activities.
 - The revised **Test Bank** contains more than 900 multiple-choice questions with text page references and answers coded for CRNE competencies and cognitive level. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by category, cognitive level, and question type; and administer and grade online tests.
 - **Revised PowerPoint Presentations** include over 1500 slides for use in lectures.
 - The **Image Collection** contains more than 1100 illustrations from the text for use in lectures.
 - **Simulation Learning System** is an online toolkit that helps instructors and facilitators effectively incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The system provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each scenario in the Simulation Learning System complements the textbook content and helps bridge the gap between lectures and clinicals. This system provides the perfect environment for students to practise what they are learning in the text for a true-to-life, hands-on learning experience.

Multimedia Supplements for Instructors and Students

- **Nursing Skills Online 2.0** contains 18 modules rich with animations, videos, interactive activities, and exercises to help students prepare for their clinical lab experience. The

instructionally designed lessons focus on topics that are difficult to master and pose a high risk to the patient if done incorrectly. Lesson quizzes allow students to check their learning curve and review as needed, and the module exams feed out to an instructor grade book. Modules cover Airway Management, Blood Therapy, Bowel Elimination/Ostomy Care, Chest Tubes, Enteral Nutrition, Infection Control, Injections, IV Fluid Administration, IV Fluid Therapy Management, IV Medication Administration, Nonparenteral Medication Administration, Safe Medication Administration, Safety, Specimen Collection,

Urinary Catheterization, Vascular Access, Vital Signs, and Wound Care. It is available alone or packaged with the text.

- **Mosby's Nursing Video Skills: Basic, Intermediate, Advanced, Version 3.0** provides 126 skills with overview information covering skill purpose, safety, and delegation guides; equipment lists; preparation procedures; procedure videos with printable step-by-step guidelines; appropriate follow-up care; documentation guidelines; and interactive review questions. It is available online as a student DVD set or as a networkable DVD set for the institution.

Acknowledgements

Developing a Canadian nursing text is an immense and exciting undertaking. In this fifth Canadian edition, every chapter has been written by expert Canadian nurses. We acknowledge the contributions of each of our Canadian authors who developed and wrote outstanding material for this edition. Their dedication and expertise is evident throughout, and we thank them for the exemplary work they did to provide to the substantiveness of this edition.

We would sincerely like to thank Dr. Janet C. Ross-Kerr and Dr. Marilyn J. Wood for their leadership and vision as the editors for Canadianizing this textbook during the past decade. We acknowledge and value their legacy as visionaries in Canadian nursing.

We also thank Kyla Janzen for her revisions to the *Study Guide* that accompanies this text.

Martina van de Velde, Managing Developmental Editor, provided excellent leadership and capable organization of all parts of the developmental process and has been extremely supportive of all the authors and editors. We are grateful to her for her skill, hard work, and dedication. We would also like to thank Clay Broeker, Senior Project Manager, for his dedication to this edition.

Ann Millar, Vice President, Publishing, is a visionary leader who was highly involved in the development of the fifth edition of *Canadian Fundamentals of Nursing*. We thank her for all her efforts; without her, this edition would not have been possible.

Health and Wellness

Written by Linda Reutter, RN (Ret.), PhD, and Kaysi Eastlick Kushner, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss ways that definitions of health have been conceptualized.
- Describe key characteristics of medical, behavioural, and socioenvironmental approaches to health.
- Identify factors that have led to each approach to health.
- Discuss contributions of the following Canadian publications to conceptualizations of health and health determinants: *Lalonde Report*, *Ottawa Charter*, *Epp Report*, *Strategies for Population Health*, *Jakarta Declaration*, *Bangkok Charter*, *Toronto Charter*.
- Discuss key health determinants and their interrelationships and how they influence health.
- Contrast distinguishing features of health promotion and disease prevention.
- Describe the three levels of disease prevention.
- Identify and give examples of the five health promotion strategies discussed in the *Ottawa Charter*.
- Analyze how the nature and scope of nursing practice are influenced by different conceptualizations of health and health determinants.

Concepts of health and what determines health have changed significantly since the 1970s. This conceptual change has major implications for Canadian nursing in the twenty-first century because how you perceive health—and what determines it—influences the nature and scope of nursing practice. The importance of health to nursing is reflected in nursing models and frameworks, in which health is one of the “metaparadigm” concepts along with *person*, *environment*, *nursing*, and, more recently, *social justice* (see Chapter 4). In each framework, health concepts are congruent with the assumptions and focus of the model.

Conceptualizations of Health

Discussion about the nature of health revolves around its relationship to *disease*, *illness*, and *wellness*. Often, debates focus on whether health is defined in negative or positive terms. When health is negatively defined as the absence of disease, health and illness are represented on a continuum, with maximum health at one end and death at the other. When health is positively defined, however, health and illness are viewed as distinct but interrelated concepts. Therefore, a person can have disease, such as a chronic pathological condition, and have healthy characteristics as well.

Many people use the words *illness* and *disease* interchangeably. Others suggest that **disease** is an objective state of ill health, the pathological process of which can be detected by medical science, whereas **illness** is a subjective experience of loss of health (Jensen & Allen, 1993; Labonte, 1993). Figure 1-1 shows the relationships among health, illness, and disease.

Definitions of health beyond the absence of disease usually have multidimensional components, including physical, mental, social, and spiritual health. Some scholars have considered this broad definition of health to be synonymous with wellness (Labonte, 1993; Pender, Murdaugh, & Parsons, 2006). Others have argued that **health** is an objective process characterized by functional stability, balance, and integrity, whereas **wellness** is a subjective experience (see discussion by Mackey, 2009). The word *health* is derived from the Old English word *hoelth*, meaning whole of body. Historically, physical wholeness was important for social acceptance, and people with contagious or disfiguring diseases were often ostracized. Good health was considered natural, whereas disease was considered unnatural. As science progressed, disease was regarded less negatively because it could be countered by scientific medicine. After World War II, the World Health Organization (WHO) (1947) in its constitution defined health as “a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity.” This is still the most commonly cited definition of health.

Classifications of Health Conceptualizations

Pender et al. (2006) classified health in three ways:

- **Health as stability.** Health is defined as the maintenance of physiological, functional, and social norms, and it relates to concepts of adaptation and homeostasis.
- **Health as actualization.** Health is defined as the actualization of human potential. Scholars and researchers who adhere to this definition often use the terms *health* and *wellness* interchangeably.
- **Health as actualization and stability.** Both actualization and stability concepts are incorporated in the definition of health as “the actualization of inherent and acquired human potential through goal-directed behaviour, competent self-care and satisfying relationships with others, while making adjustments as needed to maintain structural integrity and harmony with relevant environments” (Pender et al., 2006, p. 23).

In 1984, the WHO updated its conceptualization of health as:

the extent to which an individual or group is able, on the one hand, to realize aspirations and satisfy needs; and, on the other hand, to change or cope with the environment. Health is, therefore, seen as a resource for everyday life, not the objective of living; it is a positive

Figure 1-1 Health, illness, and disease. **Source:** From Labonte, R. (1993). *Issues in health promotion series. 3. Health promotion and empowerment: Practice frameworks* (p. 18). Toronto: Centre for Health Promotion, University of Toronto, & ParticipACTION.

concept emphasizing social and personal resources, as well as physical capacities. (p. 3)

Rather than viewing health as an ideal state of well-being (as in the 1947 WHO definition), this definition, incorporating both actualization and stability dimensions, suggests that people in a variety of situations—even those with physical disease or nearing death—could be considered healthy.

Labonte (1993) developed a multidimensional conceptualization of health that reflects both actualization and stability perspectives. Aspects include the following qualities:

- Feeling vitalized and full of energy
- Having satisfying social relationships
- Having a feeling of control over one’s life and living conditions

Figure 1-2 Dimensions of health and well-being. **Source:** From Labonte, R. (1993). *Issues in health promotion series. 3. Health promotion and empowerment: Practice frameworks* (p. 20). Toronto: Centre for Health Promotion, University of Toronto, & ParticipACTION.

- Being able to do things that one enjoys
- Having a sense of purpose
- Feeling connected to community

Using the WHO dimensions of physical, mental, and social well-being, Labonte (1993) categorized these characteristics using a Venn diagram (Figure 1-2). The diagram clearly depicts the concept of holism, whereby health is more than the sum of the component parts in that the interrelationships between and among different components result in different aspects of health.

Nurse scholars conceptualize health in different ways (see Chapter 5). For example, the McGill Model of Nursing concept of health as coping and development is very congruent with the WHO (1984) definition (Gottlieb & Gottlieb, 2007). Jones and Meleis (1993) articulated health as empowerment: “Health is being empowered to define, seek, and find conditions, resources, and processes to be an effective agent in meeting the significant needs perceived by individuals” (p. 12). This conceptualization is congruent with Labonte’s (1993) focus and reflects the essence of health promotion, to be discussed later. In a review of the concept of health, Raeburn and Rootman (2007) suggested that in view of current realities of the twenty-first century, a definition of health needs to be positive (not based on pathology or deficit), comprehensive (with a broad set of determinants), particularly attentive to the mental health dimension, and inclusive of quality of life and spirituality.

Historical Approaches to Health in Canada

Definitions of health emerge from different contexts. In modern times, the three major approaches to health have been medical,

behavioural, and socioenvironmental (Labonte, 1993). These approaches offer a useful framework for examining the evolution of health orientations in Canada.

Medical Approach

The **medical approach**, which represents a stability orientation to health, dominated Western thinking for most of the twentieth century. It emphasizes that medical intervention restores health. Health problems are defined primarily as **physiological risk factors**—physiologically defined characteristics that are precursors to or risk factors for disease. Examples include hypertension, hypercholesterolemia, genetic predispositions, and obesity. The biopsychosocial view of health (Engel, 1977) includes psychological and social elements; however, in practice, a medical focus on pathology was retained (Antonovsky, 1987). In the medical approach, the health care system is paramount to ensuring that populations remain healthy.

Focusing on treatment of disease was strongly supported after World War II, when new technological and scientific medical advances facilitated the medical approach. In Canada, postwar economic growth increased funding to build new hospitals. National health insurance was created to remove financial barriers to care. Many people believed that scientific medicine could solve most health problems and that accessible and quality health care (or, more correctly, illness care) would improve the health of Canadians. Within this approach, less emphasis was given to health promotion and disease prevention.

Behavioural Approach

By the early 1970s, increasingly large amounts of money were spent on health care, but the health status of the population did not improve proportionately. To better understand what contributed to illness and death, the Minister of Health and Welfare, Marc Lalonde, commissioned a study that resulted in the 1974 report *A New Perspective on the Health of Canadians*. This so-called *Lalonde Report* shifted emphasis from a medical to a **behavioural approach** to health. The report concluded that the traditional medical approach to health care was inadequate and that “further improvements in the environment, reductions in self-imposed risks, and a greater knowledge of human biology” were necessary to improve the health status of Canadians (p. 6). The *Lalonde Report* was the first modern government document in the Western world to acknowledge the inadequacy of a strictly biomedical health care system.

The *Lalonde Report* broadly defined health determinants as *lifestyle, environment, human biology, and the organization of health care*. This **health field concept** was widely used, modified, and expanded by other countries, and its release was a turning point in broadening Canadians’ attitudes about factors that contribute to health, along with the role of government in promoting health (Health Canada, 1998). Of the four determinants, lifestyle received the most attention, perhaps because lifestyle behaviours contributed to chronic diseases (such as cancer and heart disease) and to injuries—both of which are the leading causes of morbidity and mortality in Canada (Labonte, 1993). In addition, greater understanding of behavioural social psychology revealed factors that motivated individuals to engage in healthy or unhealthy behaviours. In 1978, the Canadian government established the Health Promotion Directorate in the Department of National Health and Welfare, the first official health promotion undertaking of its kind. Its aim was to decrease **behavioural risk factors** such as smoking,

substance abuse, lack of exercise, and an unhealthy diet. Public health programs such as Operation Lifestyle and ParticipACTION were developed through this department.

The behavioural approach places responsibility for health on the individual, thereby favouring health promotion strategies such as education and social marketing. Strategies are often based on the assumption that if people know the risk factors for disease, then they will engage in healthy behaviours. Indeed, health-enhancing practices among Canadians increased during this time. With the ParticipACTION initiative, for instance, many people increased their physical activity. Antismoking campaigns led to a substantial decrease in tobacco use.

Socioenvironmental Approach

By the mid-1980s, however, the behavioural approach to health and illness prevention fell into disfavour. Studies showed that lifestyle improvements were made primarily by well-educated, well-employed, and higher-income Canadians. The *Lalonde Report* was criticized for deflecting attention from the environment and for how environment and lifestyle were defined. Lifestyle was viewed as being within an individual's control, with health risks as "self-imposed" behaviours. This supported "victim-blaming" and views that health was largely an individual responsibility. Critics suggested that health-related behaviours could not be separated from the social contexts (environments) in which they occurred. For example, living and working conditions were perceived as barriers to engaging in healthy behaviours (Labonte, 1993).

In the **socioenvironmental approach**, health is closely tied to social structures. For example, poverty and unhealthy physical and social environments, such as air pollution, poor water quality, and workplace hazards, are recognized as influencing health directly. Thus, Canadian public health providers expanded Lalonde's (1974) health field concept to emphasize the social context of health and the relationship between personal health behaviours and social and physical environments (Hancock & Perkins, 1985).

Internationally, more attention was also given to the social context of health. The WHO Regional Conference in Europe produced a discussion paper identifying the social conditions that influence health (WHO, 1984). Just as Canada led the behavioural approach to health with the *Lalonde Report*, it was now instrumental in focusing on social and environmental conditions. In 1986, the First International Conference on Health Promotion was held in Ottawa, sponsored by the WHO, the Canadian Public Health Association (CPHA), and Health and Welfare Canada. It produced a watershed document—the *Ottawa Charter for Health Promotion*—that supported a socioenvironmental approach. This document has since been translated into more than 40 languages.

Ottawa Charter. The *Ottawa Charter for Health Promotion* (WHO, 1986) identified **prerequisites for health** as peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice, and equity. These prerequisites clearly go beyond lifestyles or personal health practices to include social, environmental, and political contexts. They place responsibility for health on society rather than only on individuals. The *Charter's* focus on social justice and equity also incorporated the concept of *empowerment*—a person's ability to define, analyze, and solve problems—as an important goal for health care providers (Registered Nurses Association of British Columbia, 1994). Indeed, Wallerstein (1992)

contended that powerlessness could be the underlying health determinant influencing other risk factors. Consequently, health promotion literature emphasizes the concept of empowerment. The *Ottawa Charter* incorporated the then-new 1984 WHO definition of health (discussed previously), which identified health as having both social and individual dimensions, emphasized its dynamic and positive nature, and viewed it as a fundamental human right (Naidoo & Wills, 1994). The *Charter* outlined five major strategies to promote health: building healthy public policy, creating supportive environments, strengthening community action, developing personal skills, and reorienting health services (detailed later in this chapter).

Achieving Health for All. Concepts from the *Ottawa Charter* were incorporated into another important Canadian document, *Achieving Health for All: A Framework for Health Promotion* (Epp, 1986). This report, developed under the leadership of Jake Epp, Minister of National Health and Welfare from 1984 to 1989, became Canada's blueprint for achieving the WHO goal of "Health for All 2000" (Figure 1-3).

Epp's (1986) report identified three major health challenges: reducing inequities, increasing prevention, and enhancing coping mechanisms. It acknowledged disparities in health, particularly between low- and high-income people, and that living and working conditions were critical determinants of health. It emphasized the need for effective ways to prevent injuries, illnesses, chronic conditions, and disabilities. Enhancing coping was an acknowledgement that the dominant diseases in Canada were chronic conditions that could not be cured. Therefore, the challenge is assisting people to manage and cope with chronic conditions in order to live meaningful and productive lives. The *Epp Report* emphasized society's responsibility for providing supports for people experiencing chronic medical conditions, stress, mental illness, and problems associated with aging, as well as the need for supports for caregivers. The report identified self-care, mutual aid, and healthy environments as ways that these challenges could be addressed, which reflected both personal and social responsibility. Specific strategies to address the challenges included fostering public participation, strengthening community health services, and coordinating healthy public policy.

The *Ottawa Charter* and the *Epp Report* each reflect a **socioenvironmental approach** in which health is seen as more than just the absence of disease and engaging in healthy behaviours; rather, this approach emphasizes connectedness, self-efficacy, and capacity to engage in meaningful activities (see Figure 1-2).

Risk Factors and Risk Conditions. Labonte (1993) categorized the major determinants of health in a socioenvironmental approach as psychosocial risk factors and socioenvironmental risk conditions:

- **Psychosocial risk factors** are complex psychological experiences resulting from social circumstances that include isolation, lack of social support, limited social networks, low self-esteem, self-blame, and low perceived power.
- **Socioenvironmental risk conditions** are social and environmental living conditions that include poverty, low educational or occupational status, dangerous or stressful work, dangerous physical environments, pollution, discrimination, relative political or economic powerlessness, and inequalities of income or power.

According to a socioenvironmental approach to health, political, social, and cultural forces affect health and well-being

Figure 1-3 Achieving health for all: A framework for health promotion. **Source:** From Epp, J. (1986). *Achieving health for all: A framework for health promotion* (p. 8). Ottawa: Health and Welfare Canada. Reproduced with the permission of the Minister of Public Works and Government Services Canada, 2012.

both directly and indirectly through their influence on personal health behaviours. Socioenvironmental risk conditions can contribute to psychosocial risk factors, which can then result in unhealthy behaviours (Figure 1-4). This means that health care providers should recognize the influence of environment on personal behaviours and that “health-inhibiting” behaviours could be coping strategies for managing the stress created by living and working conditions that decrease access to resources. In other words, “to change behaviour it may be necessary to change more than behaviour” (Wilkinson, 1996, p. 64). For example, in addition to working “downstream” to assist people who are experiencing the negative health effects of socioenvironmental conditions, nurses need to work “upstream” by advocating for policies that ensure affordable housing, financial support to patients with low incomes, and safe, fulfilling work environments.

Strategies for Population Health. In Canada, the determinants of health have been further emphasized through the **population health approach**. This approach, initiated by the Canadian Institute for Advanced Research, was officially endorsed by the federal, provincial, and territorial ministers of health in the report titled *Strategies for Population Health: Investing in the Health of Canadians* (Federal, Provincial, and Territorial Advisory Committee on Population Health [ACPH], 1994). In a population health approach, “the entire range of known individual and collective factors and conditions that determine population health status, and the interactions among them, are taken into account in planning action to improve health” (Health Canada, 1998). The population health approach emphasizes the use of epidemiological data to determine the etiology of health and disease.

The key health determinants identified in the *Strategies for Population Health* report are as follows:

- Income and social status
- Social support networks
- Education
- Employment and working conditions
- Physical environments
- Biology and genetic endowment
- Personal health practices and coping skills
- Healthy child development
- Health services

In 1996, Health Canada added *gender, culture, and social environments* to this list. Note that the list includes determinants at the individual level (personal health practices and coping skills; biology and genetic endowment) and at the population level (education, employment, and income distribution).

Jakarta Declaration. The *Jakarta Declaration on Health Promotion Into the 21st Century* (WHO, 1997) emerged from the 4th International Conference on Health Promotion, the first to be held in a developing country and to involve the private sector. The *Jakarta Declaration* affirmed the *Ottawa Charter* prerequisites for health; added four other prerequisites (*empowerment of women, social security, respect for human rights, and social relations*); and declared poverty to be the greatest threat to health. The Declaration identified the following priorities for action: promoting social responsibility for health in public and private sectors; increasing investments for health in all sectors; consolidating and expanding partnerships for health to all levels of government and the private sector; increasing community capacity and empowering the individual; and securing adequate infrastructure for health promotion.

Bangkok Charter. The *Bangkok Charter for Health Promotion in a Globalized World* (WHO, 2005) affirmed health as a human right and emphasized mental and spiritual well-being

Figure 1-4 Socioenvironmental approach to health. **Source:** From Labonte, R. (1993). *Issues in health promotion series. 3. Health promotion and empowerment: Practice frameworks* (p. 11). Toronto: Centre for Health Promotion, University of Toronto, & ParticipACTION.

as important elements. It identified critical factors influencing health, such as the increasing inequalities within and between countries, global environmental change, and urbanization. The *Charter* emphasized strong political action and sustained advocacy, empowering communities with adequate resources, and corporate sector commitment to healthy workplaces and ethical business practices.

Toronto Charter. In the early to middle 1990s, Canadian social and health policies resulted in increased social and economic inequalities (Bryant, 2002; Raphael, 2009a) and health disparities. These concerns culminated in the *Toronto Charter on the Social Determinants of Health*, which identified the following social determinants as particularly important for health: Aboriginal status, early life, education, employment and working conditions, food security, gender, health care services, housing, income and its distribution, social safety net, social exclusion, and unemployment and employment security. **Social determinants of health** can be defined as “the economic and social conditions that shape the health of individuals, communities, and jurisdictions as a whole . . . [and] determine the extent to which a person possesses the physical, social, and personal resources to identify and achieve personal aspirations, satisfy needs, and cope with the environment” (Raphael, 2009a, p. 2; italics ours). This conceptualization of health determinants emphasizes societal responsibility for reducing health disparities because it focuses on how a society distributes economic and social resources through its economic and social policies. A social determinants of health perspective calls attention to the political, economic, and social forces that shape policy decisions, thereby reflecting a critical/structural approach to health (Bryant, 2009b). The social determinants of health identified in the *Toronto Charter* were chosen because they (a) are important to the health of Canadians, (b) are

understandable to Canadians, (c) have clear policy relevance to decision makers and citizens, and (d) are especially timely and relevant (Raphael, 2009a).

Concern about **health disparities** (i.e., differences in health status among different population groups) has been raised worldwide. The WHO Commission on Social Determinants of Health (WHO, 2008a) was charged with developing strategies to narrow health disparities through action on the social determinants of health. Nationally, the Health Disparities Task Group (2005), commissioned by the Public Health Agency of Canada (PHAC), identified socioeconomic status, Aboriginal identity, gender, and geographic location as the most important factors contributing to health disparities. In 2007, the Senate Subcommittee on Population Health was established to examine the impact of social determinants of health on disparities and inequities in health (Senate Subcommittee on Population Health, 2009). The *Report on the State of Public Health in Canada* (PHAC, 2008) by Canada’s first chief public health officer also underscored health inequalities.

Health disparities are associated with inequitable access (unfair or unjust lack of access) to health determinants resulting from economic and social policies; therefore, the term *health inequities* (rather than *health inequalities* or *disparities*) may more accurately reflect the source and nature of health differences (Reutter & Kushner, 2010b).

Determinants of Health

The following section introduces you to some of the major determinants of health affecting Canadians (Health Canada, 1996). Although each determinant on its own contributes to health, the determinants are also interrelated and influence each other.

Income and Social Status (Income Distribution)

Income and social status is the greatest **determinant of health** because it influences most other determinants (Canadian Institute for Health Information [CIHI], 2004; Raphael, 2009a). According to Statistics Canada after-tax low-income cut-offs in 2008, 9% of Canadians lived in poverty, with much higher rates among single mothers (21%) and unattached nonelderly women (36%) and men (28%) (National Council of Welfare, 2008). Aboriginal peoples, Canadians of colour, people with disabilities, and recent urban immigrants also have much higher rates of poverty compared to the Canadian average (see summary by Raphael, 2006).

Poverty exerts its effect on health through lack of material resources that support health, through higher levels of psychosocial stress, and through health-threatening behaviours to cope with limited resources and stress (Raphael, 2009a). Low-income Canadians are more likely to die early and to suffer from most diseases, regardless of age, sex, race, culture, or place of residence (Phipps, 2003). It is estimated that 23% of Canadians' premature loss of life can be accounted for by income differences (Raphael, 2009a). People with lower incomes are more likely to have chronic health problems, particularly cardiovascular disease and type 2 diabetes (Raphael et al., 2003; Raphael & Farrell, 2002; Wilkins et al., 2002); lower self-esteem, lower sense of mastery and coherence; and higher levels of depression (Federal, Provincial, and Territorial ACPH, 1999). With each step up the economic ladder, Canadians' health status improves, suggesting that this "social gradient" of health is related to more than absolute material deprivation (Raphael, 2009b).

Low birth weight, an important marker for subsequent poor child and adult health, has a 43% higher incidence in poor neighbourhoods than in higher-income neighbourhoods (Wilkins et al., 2002). Children living in poverty are more likely to have chronic diseases such as asthma, to visit emergency rooms, and to die from injuries (Canadian Institute of Child Health, 2000) and are at greater risk for cognitive difficulties, delayed vocabulary development, and behavioural problems (CIHI, 2004).

Income inequality (i.e., the increasing gap between the rich and the poor [Curry-Stevens, 2009]) also influences population health. Countries with greater economic inequality have lower overall health and life expectancies (Wilkinson & Pickett, 2009). Although the mechanisms responsible for this association are complex and still being explored, one explanation suggests that income inequality may result in less public investment in sectors that affect health, such as education, health services, transportation, and housing (Auger & Alix, 2009).

Social Support Networks

Social support affects health, health behaviours, and health care utilization (Carpiano, 2007; Mikkonen & Raphael, 2010) through practical, emotional, informational, and affirmational support (House, 1981). Indeed, some experts believe that relationships may be as important to health as established risk factors such as obesity, smoking, and high blood pressure (Federal, Provincial, and Territorial ACPH, 1999). A strong body of research links social support with positive health outcomes (Carpiano, 2007; Richmond et al., 2007; Tomaka et al., 2006); whereas social isolation, exclusion, and lack of supportive relationships increase stress and vulnerability to disease directly, as well as indirectly through increased risk behaviours

such as smoking, substance abuse, and overeating (Mikkonen & Raphael, 2010).

In general, Canadians have reported high levels of support (Federal, Provincial, and Territorial ACPH, 1999). Four of five Canadians reported they had someone to confide in, whom they could count on in a crisis or for advice, and who made them feel loved and cared for. Nevertheless, men, single parents, and lower-income Canadians generally reported less support than did their respective counterparts. Support from families and friends and from informal and formal groups can provide practical aid during times of crisis and emotional support in times of distress and change. Social support assists coping and behavioural changes and can help individuals solve problems and maintain a sense of mastery and control over their lives. A Canadian population-based study found that higher levels of support and mastery were associated with lower psychological distress for men and women (Gadalla, 2009). A survey of young parents in Alberta identified spouses, family, and friends as major sources of support in encouraging healthy behaviours (exercise, diet) by providing emotional, affirmational, and practical support, including child care and financial assistance (Reutter et al., 2001). Support interventions helped mothers of very preterm infants gain confidence in their parenting skills and understand their infants' medical conditions (Preyde, 2007) and helped low-income women reduce or quit smoking (Stewart, Kushner, et al., 2010). It is important to address social support in relation to not only individual behaviours but also the broader social, political, and economic context that shapes community norms, values, and behaviours (Richmond, 2007; Richmond & Ross, 2009).

Education and Literacy

Education and literacy are important influences on health status because they affect many other health determinants. Literacy can influence health both directly (e.g., reading medication prescriptions, baby formula instructions, safety instructions in workplaces) and indirectly through use of services, personal health practices, income, work environments, and stress levels. For example, people with low literacy skills are more likely to be unemployed, receive income support, earn minimum wages in unskilled jobs, have higher stress levels, and make less use of preventive services (Ronson & Rootman, 2009). Education increases job opportunities and income security, which provide knowledge and skills to solve problems and gain a sense of control (PHAC, 2004). People with higher education levels tend to smoke less, be more physically active, and have access to healthier foods and physical environments (Federal, Provincial, and Territorial ACPH, 1999).

Employment and Working Conditions

Employment and working conditions significantly affect physical, mental, and social health. Paid work provides financial resources, a sense of identity and purpose, social contacts, and opportunities for personal growth (Smith & Polanyi, 2009). Unemployment is linked to material and social deprivation, adoption of health-threatening coping behaviours, psychological stress, and physical and mental health problems (Mikkonen & Raphael, 2010).

Working conditions can support health or pose health hazards. Smith and Polanyi (2009) identified available, adequate, appropriate, and appreciative work as pillars of workplace health. Healthy workplaces include job and employment security, safe physical conditions, reasonable work pace, low

stress, opportunities for self-expression and individual development, participation, and work-life balance (Jackson, 2009). Temporary employees, part-time workers, and people working in low-wage jobs have high levels of job insecurity and frequent periods of unemployment. Often such jobs do not provide benefits or pensions, which can lead to uncertainty and stress (Menendez et al., 2007; Tompa et al., 2007). In 2000, more than one in four Canadian workers believed that their place of work was not healthy (Canadian Policy Research Networks, 2008). One-third of Canadian workers in 2003 reported high stress at work, with even higher rates (45%) for health care workers (Wilkins, 2007). Indeed, the concern regarding negative workplace conditions in the health sector is considerable; nurses have had the highest or second-highest rates of absenteeism of all workers in Canada since the early 1990s (Villeneuve & MacDonald, 2006). Workplace stress is linked to increased risk of physical injuries, high blood pressure, cardiovascular disease, depression, and increases in tobacco and alcohol use (Jackson, 2009). In 2003, almost 10% of Canadian workers in trades, transport, and equipment operation sustained on-the-job injuries, which is more than four times the rate among workers in the “white-collar” sector (Wilkins & Mackenzie, 2007).

Physical Environments

Housing, indoor air quality, and community planning are important determinants of health. Contaminants in air, water, food, and soil also adversely affect health, sometimes contributing to cancer, birth defects, respiratory illness, and gastrointestinal ailments. Children from low-income families, who often live in substandard housing and in neighbourhoods near highways and industrial areas, are particularly likely to be exposed to these contaminants (Center for Quality Growth and Regional Development, 2006). Asthma, which is characterized by high sensitivity to airborne contaminants, is the most common chronic respiratory disease among children, accounting for 25% of all school absenteeism (Canadian Council on Social Development, 2006); children in poverty are particularly vulnerable to this disease (Lethbridge & Phipps, 2005).

Involuntary exposure to tobacco smoke (second-hand smoke) has received considerable attention in Canada. There is no safe level of exposure to second-hand tobacco smoke (WHO, 2009). It can increase children's risk for sudden infant death syndrome, acute respiratory infections, ear problems, and reduced lung development, and can increase adults' risk for coronary heart disease and lung cancer (US Department of Health and Human Services, 2006). Municipalities throughout Canada have incorporated smoking bans in public places (and in several jurisdictions, smoking bans in private cars when children are present). In 2005, 23% of nonsmokers reported regular exposure in at least one venue (public place, home, or vehicles), and children were at highest risk for exposure (Shields, 2007).

Another important aspect of the environment is affordable, suitable, and adequate housing. Homelessness in Canada is increasing, in part because of reduced government funding of social housing and lack of affordable rental accommodation (Bryant, 2009a; Khandor & Mason, 2007). Homeless populations are at greater risk for a variety of health problems, including mental illness, substance abuse, suicide, tuberculosis, injuries and assaults, chronic medical conditions (e.g., respiratory and musculoskeletal), and poor oral and dental health, and for early death (Frankish et al., 2005; Khandor & Mason,

2007). Inadequate and insecure housing can affect health *directly* (e.g., presence of lead, asbestos, poor heating systems, overcrowding, dampness) and *indirectly* through its influence on other determinants (Bryant, 2009a). Spending a disproportionate amount of income on rent, for example, reduces the amount of money that families can spend on food, clothing, recreation, and health care. The determinant of physical environment also includes the effects of climate change on the health of populations and the planet itself. The Canadian Nurses Association has produced several documents related to nursing's role in addressing climate change (2008, 2009), including an excellent video and educational module available on its Web site. The need for sustainable ecosystems, a prerequisite for health first identified in the *Ottawa Charter*, is clearly becoming more critical; however, the relationship between human and environmental health is a relatively recent focus for nursing (Hansen-Ketchum, et al., 2009).

Biological and Genetic Endowment

Heredity is strongly influenced by social and physical environments, and considerable effort has been expended to prevent congenital defects through monitoring and improved preconception and prenatal care (Federal, Provincial, and Territorial ACPH, 1999). This effort has led to substantial decreases in anomalies at birth. Yet, there is also increasing recognition that nature and nurture are not dichotomous influences on health but that “the social environment has a profound impact upon the function of one's genes, providing the context and stimulus for the variable expression of an inherited code” (Denburg & Daneman, 2010, p. 28).

Age is also a strong determinant of health. Many older people develop chronic diseases, although disability can be reduced with healthy aging (Healthy Aging and Wellness Working Group, 2006). Indeed, 70% of older people in Canada report good overall health, including good functional health and independence in activities of daily living (Shields & Martel, 2006). Nurses need to consider how much of the decline associated with aging is related to biological aging versus other determinants such as socioeconomic status, social support, and individual health practices.

Individual Health Practices and Coping Skills

Effective coping skills help people face challenges without resorting to risk behaviours such as substance abuse. Many so-called risk behaviours may, in fact, be coping strategies for stress and strain caused by living circumstances. For example, considerable evidence reveals that low-income women use smoking as a coping strategy (Stewart et al., 2011). Three risk behaviours with major detrimental health consequences are physical inactivity, poor nutrition, and tobacco use.

Physical inactivity is a major risk factor for some types of cancer, diabetes, cardiovascular disease, osteoporosis, obesity, hypertension, depression, stress, and anxiety. In 2004, just over half (52%) of Canadians aged 12 and older were at least moderately active during their leisure time (equivalent to walking at least 30 to 60 minutes a day). Those who were active were more likely to rate their health as excellent or very good and to report lower levels of stress and were less likely to be overweight, obese, or hypertensive (Gilmour, 2007). However, actual physical measures of activity using accelerometer technique revealed that only 15% of Canadian adults meet the recommendation of 150 minutes of MVPA (moderate to vigorous physical activity) weekly (Colley et al., 2011b) and only 7%

of children achieve the recommendation of 60 minutes of MVPA at least 6 days per week (Colley et al., 2011a). *Poor nutrition*, particularly overconsumption of fats, sugars, and salt, is linked to such diseases as some cancers, cardiovascular diseases, type 2 diabetes, hypertension, osteoarthritis, and gallbladder disease and to functional limitations and disabilities (Tjepkema, 2006). Obesity is considered to be a major public health threat, and in 2010, the federal government launched a country-wide intersectoral initiative to curb child obesity (PHAC, 2010). The 2004 Canadian Community Health Survey (CCHS) revealed that 23% of adult Canadians were obese (body mass index [BMI] of 30 or more) and 36% were overweight (Shields, 2006); as BMI increased, so did the likelihood of reporting high blood pressure, diabetes, and heart disease. About 26% of children (aged 2–17 years) were overweight or obese (Shields, 2006). The 2004 CCHS (Nutrition section) revealed that 70% of children aged 4–8 years ate fewer than the minimum five servings of vegetables and fruit daily. Moreover, 25% of Canadians overall (and one-third of teenagers aged 14–18) had eaten at fast-food outlets the previous day (Garriguet, 2007), which feature foods high in fats and salt. Several factors influence food consumption patterns, including household income, food advertising, and availability of nutritious choices. *Food insecurity* (the limited or uncertain availability of nutritious foods) is a growing problem in Canada. In 2004, more than 40% of households with low or lower middle incomes reported food insecurity (Ledrou & Gervais, 2005); those receiving social assistance were particularly vulnerable. In March 2010, over 800,000 Canadians were assisted by food banks, a 9% increase over 2009 and the highest level on record. Over half (51%) of these users were social assistance recipients, and 51% were families with children, half of whom were two-parent families (Food Banks Canada, 2010). Food insecurity is significantly associated with multiple chronic conditions, distress, and depression (Tarasuk, 2009).

Tobacco use remains the leading preventable cause of death and disease in Canada (Makamowski Illing & Kaiserman, 2004). It is the only legal consumer product that can harm everyone exposed to it—and it kills up to half of those who use it as intended (WHO, 2008b). For every person who dies from smoking, another 20 continue to suffer with at least one serious tobacco-related illness, such as coronary heart disease, lung diseases, and cancers (US Department of Health and Human Services, 2010). The smoking rate in Canada in 2009 was 18% (Health Canada, 2011b), but this burden is over-represented in more vulnerable populations, including those living in poverty (Physicians for a Smoke-free Canada, 2005) and Aboriginal people (Health Canada, 2011a). Half of all people with mental illness smoke, of whom 40% smoke more than 25 to 30 cigarettes per day, compared with 15% in the general population (de Leon & Diaz, 2005).

Clearly, many factors influence individual health behaviours (e.g., income, education, culture, and social support). Developing and maintaining health-enhancing behaviours requires not only health education but also social policies related to income security, product marketing, and supportive environments that make healthy choices the “easy” choices. In short, education is a necessary but not sufficient strategy.

Healthy Child Development

All determinants influence child development, but healthy child development is a separate determinant because of its importance to lifelong health. Increasing evidence reveals that

events during conception and through the age of 6 years influence children’s health for the rest of their lives (CIHI, 2004; Gluckman et al., 2010; Halfon et al., 2010; McCain et al., 2007). Three conditions for healthy child development are adequate and equitable income, effective parents and families, and supportive community environments (CIHI, 2004; Conroy et al., 2010).

Conception through the early years of childhood constitutes a critical period for biological and brain development that strongly shapes learning, behaviour, and health over the life course (McCain et al., 2007). Children raised in adverse environments are predisposed to coronary health disease, hypertension, type 2 diabetes, substance abuse, and mental health problems (McCain et al., 2007). Throughout the toddler, preschool, and school-age years, meeting a child’s development needs is crucial. Family environment is important, particularly establishing attachment to a primary caregiver who provides a basis for emotional and social well-being. Family conflict, violence, and poverty threaten healthy child development. Schools in which students feel secure, respected, challenged, and cared for help ensure that children succeed academically. Community support is also important (McCain et al., 2007).

Quality early childhood education and care are particularly important in early child development, so much so that they have been singled out by some researchers as a combined social determinant of health (Friendly, 2009). High-quality programs promote cognitive development and social competence and support parents in education and employment. Canada has acknowledged the importance of early childhood intervention through its Early Childhood Development Initiative (Health Council of Canada, 2006); however, Canada lacks a national child care program.

Health Services

Approximately 25% of a population’s health status is attributed to the health care services (Senate Subcommittee on Population Health, 2009). Quality and accessible primary care, hospital care, long-term care, home care, and public health services are therefore important. Prenatal care, well-child and immunization clinics, education services about health practices, and services that maintain older adults’ health and independence are important examples of preventive and primary health care services (discussed further in Chapters 2 and 4). Principles of the *Canada Health Act*—universality, portability, accessibility, comprehensiveness, and public administration—apply to hospital and physician services, which cover only 70% of total health care costs. Medicare does not cover drug costs or dental care, and home care coverage varies across provinces (Mikkonen & Raphael, 2010), contributing to inequitable access. Increasingly, the trends in health care service provision are from institutionalized care to community-based care, toward decision making that is based on the best available evidence, and toward more regional administration. Considerable monies have been invested in initiatives that incorporate principles of primary health care; however, the progress in this regard has been relatively slow (Health Council of Canada, 2011).

Gender

Gender is “the array of society-determined roles, personality traits, attitudes, behaviours, values, relative power, and influence that society ascribes to the two sexes on a differential basis” (PHAC, 2004) and must examine men’s as well as

women's experiences (Bates et al., 2009). Many health issues are a function of gender-based social roles, and gender can influence health status, behaviours, and care (Armstrong, 2009; Bates et al., 2009; Spitzer, 2005); gender also influences all other health determinants (Armstrong, 2009). In Canada, men are more likely than women to experience extreme forms of social exclusion and to die prematurely, largely as a result of heart disease, unintentional fatal injuries, cancer, and suicide. Women, however, are more likely to suffer from depression, stress (often resulting from efforts to manage paid and family work), chronic conditions such as arthritis and allergies, and injuries and death from family violence (Federal, Provincial, and Territorial ACPH, 1999; Mikkonen & Raphael, 2010). Moreover, gender influences men's and women's experience of sex-specific health concerns (e.g., pregnancy, prostate cancer, presentation of cardiovascular signs and symptoms), exposure to potential risk conditions (e.g., caregiving demands as traditionally women's responsibility), and interactions with health care providers (e.g., gender stereotypes, medicalization of health experience) (Pederson & Raphael, 2006).

Culture

Cultural and ethnic factors influence people's interactions with a health care system, their participation in prevention and health promotion programs, their access to health information, their health-related lifestyle choices, and their understanding of health and illness (Health Canada, 1996). Cultural factors also influence whether and how determinants are met (see Chapter 9). Among immigrants and refugees, health is negatively affected by unmet expectations, challenges to successful social integration, and difficulties arising from underemployment or unemployment, low income, and food and housing insecurity (Anderson et al., 2010; Dean & Wilson, 2009; Mikkonen & Raphael, 2010; Stewart, Makwarimba, et al., 2010). Language differences can lead to isolation and decreased social support networks. Prejudice can cause individuals to be denied opportunities for education, employment, and access to housing (Health Canada, 1996). Aboriginal peoples are much more likely to suffer acute and chronic diseases and experience higher infant mortality and shorter life expectancy than the general Canadian population (Mikkonen & Raphael, 2010). It is important to acknowledge the intersection of culture with other health determinants such as social support, employment, and income.

Social Environments

Social environments are defined as "the array of values and norms of a society [that] influence in varying ways the health and well-being of populations. In addition, social stability, recognition of diversity, safety, good working relationships, and cohesive communities provide a supportive society that reduces or avoids many potential risks to good health" (PHAC, 2004). The social environment is clearly related to other factors and expands on the social support determinant by incorporating broader community characteristics, norms, and values. Healthy social environments include freedom from discrimination and prejudice—particularly for people marginalized by income, age, gender, activity limitations, ethnicity, and sexual orientation. The determinant of social environment is also evident in the *Jakarta Declaration's* prerequisites of human rights, social security, and social relations (WHO, 1997). These prerequisites relate to social exclusion—the process by which people are denied opportunities to participate in many aspects

of cultural, economic, social, and political life (Galabuzi, 2004). People most likely to be excluded are poor citizens, Aboriginal people, new Canadians, and members of racialized or non-white groups. Social exclusion limits people's access to the resources that support health and their participation in community life (Stewart et al., 2008). A sense of community belonging has been linked to better self-rated general health and mental health (Shields, 2008).

Another important aspect of the social environment is the absence of violence, both in the home and in the community. In 2004, 7% of Canadians aged 15 years and older had experienced spousal violence in the previous five years; Aboriginal people were at a three-fold greater risk, and women were more likely to suffer from serious types of violence. Children accounted for 21% of cases of physical assault and 61% of cases of sexual assault, and close to 40% of elderly women suffered some kind of assault from family members (Canadian Centre for Justice Statistics, 2005). The health effects of family violence are devastating, for those experiencing or exposed to violence and for the perpetrators, and include psychological, physical, behavioural, academic, sexual, interpersonal, self-perceptual, or spiritual consequences, which may appear immediately or over time (Department of Justice Canada, 2009).

Violence is also experienced in other venues, particularly schools and workplaces. More than one-third (36%) of Canadian students in grades 6–10 reported being victims of bullying. Victimized children are at risk for anxiety, depression, loss of self-esteem, and somatic complaints; perpetrators are also at risk for long-term problems such as antisocial behaviour and substance use (Craig & Edge, 2008). Health care workers, including nurses, have experienced violence perpetrated by clients, family members, and co-workers (Duncan et al., 2001; Shields & Wilkins, 2009).

Strategies to Influence Health Determinants

Health Promotion and Disease Prevention

The understanding that health is qualitatively different from disease has led to a differentiation of the concepts of health promotion and disease prevention, although they are interrelated. Pender et al. (2006) differentiated between health promotion and disease prevention as follows: **health promotion** is "directed toward increasing the level of well-being and self-actualization" (p. 37); **disease prevention** (particularly primary prevention) is "action to avoid illness/disease" (p. 36). On the other hand, Leavell and Clark's (1965) initial conceptualization of levels of prevention considered health promotion as one aspect of primary prevention and not necessarily disease specific. In contrast, the *Ottawa Charter* views health promotion as the overarching concept, defined as "the process of enabling people to increase control over, and improve, their health" (WHO, 1986). The following more comprehensive definition was offered by Nutbeam (1998):

Health promotion represents a comprehensive social and political process, it not only embraces actions directed at strengthening the skills and capabilities of individuals, but also action directed towards changing social, environmental and economic conditions so as to alleviate their impact on public and individual health. Health promotion is the process of enabling people to increase control over the determinants of health and thereby improve their health. Participation is essential to sustain health promotion action. (p. 351)

Three levels of disease prevention correspond to the natural history of disease:

- *Primary prevention* activities protect against a disease before signs and symptoms occur (prepathogenesis stage of disease). Examples include immunization (to prevent infectious diseases) and reduction of risk factors (such as inactivity, smoking, and exposure to air pollution).
- *Secondary prevention* activities promote early detection of disease once pathogenesis has occurred, so that prompt treatment can be initiated to halt disease and limit disability. Examples include preventive screening for cancer (e.g., mammography, testicular self-examination); blood pressure screening to detect hypertension; and blood glucose screening to detect diabetes.
- *Tertiary prevention* activities are initiated in the convalescence stage of disease and are directed toward minimizing residual disability and helping people to live productively with limitations. An example is a cardiac rehabilitation program after a myocardial infarction.

Nursing strategies guided by a prevention framework focus on assessment and alleviation of risk factors for disease. On the other hand, health promotion may be viewed more broadly than disease prevention inasmuch as it emphasizes participation, empowerment, and equity and goes beyond individual health education to a broader ecological approach that incorporates community development and policy advocacy. Health promotion strategies, therefore, are often political because they emphasize addressing structural and systemic inequities and have a strong philosophy of social justice. Health promotion is guided by the following principles (CPHA, 1996):

- Health promotion addresses health issues in context.
- Health promotion supports a holistic approach.
- Health promotion requires a long-term perspective.
- Health promotion is multisectoral.
- Health promotion draws on knowledge from social, economic, political, environmental, medical, and nursing sciences, as well as from first-hand experiences.

Health Promotion Strategies

The *Ottawa Charter* identified five broad strategies to enhance health. The following is a brief introduction to each of these **health promotion strategies**. For further examples of each of these strategies see Reutter and Kushner (2010a).

1. Build Healthy Public Policy. Advocating healthy public policies is a priority strategy for health promotion in Canada. Indeed, some academics have suggested that this strategy is the foundation of all others because policies shape how money, power, and material resources are distributed to society (CPHA, 1996). Advocating healthy public policy means focusing on policies that create healthy living conditions. Because the determinants of health are broad, healthy public policy necessarily extends beyond traditional health agencies and government health departments to other sectors such as agriculture, education, transportation, labour, social services, energy, and housing. Therefore, policymakers in all government sectors and organizations should ensure that their policies have positive health consequences. This emphasis is reflected in national and international documents, including the recent *Adelaide Statement on Health in All Policies* (WHO, 2010). Advocating healthy public policy is best addressed through intersectoral collaboration. As a nurse, you might work with others to develop policy options, encourage public

BOX 1-1 NURSING STORY

Cathy Crowe: Advocating Healthy Public Policy

Cathy Crowe is a Toronto street nurse who has advocated for policies related to a variety of social determinants. Her work as an outreach street nurse in Toronto since the 1980s exemplifies nursing's role not only in attending to immediate health needs of people who are homeless but also advocating for policies that will provide more adequate and affordable housing to alleviate the root causes of these health problems. Crowe co-founded the Toronto Disaster Relief Committee (TDRC) in 1998, which declared homelessness a national disaster in Canada. The committee advocated a "1% solution," calling on the federal, provincial, and territorial governments to allocate an additional 1% of their budget to fully fund a national affordable housing program. The efforts of the TDRC increased awareness, both in large cities in Canada and at the United Nations, of Canada's housing problem. This awareness led to the appointment of a federal minister responsible for homelessness and federal emergency relief monies (e.g., for shelter beds, food banks, programs for homeless youth). Although monies were also made available to provide housing, the goal of a fully funded national housing strategy has not yet been realized, and homelessness continues to increase across Canada.

Crowe has fostered numerous coalitions and advocacy initiatives, working with homeless people and other organizations. The TDRC was involved in fighting the evictions of Toronto's Tent City in 2002 and succeeded in eventually securing housing for many residents. Crowe is currently on the board of directors of a nonprofit organization that is building affordable housing in Toronto. To raise awareness about children who are homeless, she co-produced the film *Home Safe*, set in several Canadian cities. As part of this initiative, a children's forum on homelessness was organized to provide children the opportunity to voice their concerns to the United Nations Special Rapporteur on Adequate Housing when he visited Canada. Crowe has also written a book, *Dying for a Home*, co-authored with activists who are homeless themselves.

Crowe has received numerous awards for her advocacy work. She sees advocacy as a critical nursing role and responsibility. You are encouraged to view her many speeches and activities on her Web site at <http://cathycrowe.ca>.

dialogue, persuade decision makers to adopt the healthiest option, and follow up to make sure the policy is implemented (CPHA, 1996). Cathy Crowe, a Toronto "street nurse," is an excellent example of a nurse who advocates for healthy public policy to reduce homelessness (Box 1-1).

Increasingly, policy advocacy is incorporated into nursing role statements (e.g., Canadian Public Health Association, 2010; International Council of Nurses, 2001) and nursing education curricula (Rains & Barton-Kriese, 2001; Reutter & Duncan, 2002; Reutter and Kushner, 2010b; Reutter & Williamson, 2000). In your nursing care, it is important to think about what policies have contributed to the health situations of your patients, what policies would help alleviate health problems, and how you can champion public policies. For example, how do current welfare incomes, which are lower than poverty "lines" (low-income cut-offs), influence recipients' abilities to obtain adequate food and shelter and participate meaningfully in Canadian society? An informative resource on policy implications arising from social determinants of health is *Social Determinants of Health: The Canadian Facts* (see website at the end of the chapter). Reutter and Kushner (2010b) provide suggestions

for the nursing role in policy advocacy, while Cohen and Reutter (2007) outline ways that nurses can engage in policy advocacy specifically related to child and family poverty.

2. Create Supportive Environments. The *Ottawa Charter* (WHO, 1986) states that “the overall guiding principle . . . is the need to encourage reciprocal maintenance, to take care of each other, our communities and our natural environment” (p. 2). This strategy helps ensure that physical environments are healthy and safe and that living and working conditions are stimulating and satisfying. Creating supportive environments also means protecting the natural environment and conserving natural resources (WHO, 1986).

An excellent example of an initiative that helps create supportive environments is the Comprehensive School Health Initiative, which focuses on improving school environments by providing health instruction, social support, support services, and positive physical environments (Mitchell & Laforet-Fliesser, 2003). Other examples of supportive environments include flexible workplace policies, quality child care programs that support early child development and parental employment, and baby- and senior-friendly community initiatives.

3. Strengthen Community Action. Strengthening communities is a requisite for successful health promotion and for community health nursing practices in Canada (Canadian Public Health Association, 2010). In this strategy, often referred to as *community development*, communities identify issues and work together to make changes that will enhance health. In a community development approach, health providers help community groups identify important issues and organize and implement plans and strategies to resolve these issues, often partnering with other community organizations (see Chapter 4). Public participation in all phases of community programming is key to community development. Examples of community development projects are community gardens and collective kitchens targeted to enhancing food security.

4. Develop Personal Skills. This strategy, which is probably most familiar to nurses, helps clients develop

personal skills, enhance coping strategies, and gain control over their health and environments so that they can make healthy lifestyle choices. Personal skills development includes health education, but it also emphasizes adequate support and resources. Some examples of interventions to enhance personal skills include early intervention programs for children, home visiting by public health nurses, parenting classes, and falls reduction programs for seniors. On a broader level, examples include province-wide health communication initiatives aimed at improving nutrition and physical activity (e.g., *Healthy U* [Alberta], *Act Now* [B.C.]).

5. Reorient Health Services. Health system reform has two objectives: to shift emphasis from treating disease to improving health and to make the health care system more efficient and effective (CPHA, 1996). A proactive approach to health requires improved access to primary health care services, increased community development, improved community-based care services, increased family-based care, and public participation. In Canada, there is considerable emphasis on developing the primary health care model, which nursing associations have advocated for many years (Reutter & Ogilvie, 2011; see also Chapters 2 and 4). Several Canadian documents have reiterated the urgency for the health sector to reorient its focus beyond provision of health care to reducing health inequities through action on the social determinants of health (e.g., Health Council of Canada, 2010; Health Disparities Task Group, 2005).

Population Health Promotion Model: Putting It All Together

This chapter has presented two major approaches to health: health promotion and population health. Hamilton and Bhatti (1996) integrated these two concepts into one model that shows their relationship to each other (Figure 1-5). Aimed at developing actions to improve health, the model explores four major questions: “On *what* can we take action?”; “*How* can we

Figure 1-5 Population health promotion model. **Source:** From Hamilton, N., & Bhatti, T. (1996). *Population health promotion: An integrated model of population health and health promotion*. Ottawa: Health Promotion Development Division, Health Canada. Copyright © 1996 by Minister of Public Works and Government Services Canada.

take action?"; "With *whom* can we act?"; and "Why take action?" (Saskatchewan Health, Population Health Branch, 2002).

The document *Strategies for Population Health* (Federal, Provincial, and Territorial ACPH, 1994) indicates health determinants actions that could be taken (the "what"). The *Ottawa Charter* provides a comprehensive set of five strategies to enhance health (the "how"). Together, these documents suggest that to enhance population health, action must be taken on a variety of levels (the "who"). Clearly, nurses must direct these strategies toward individuals and families, communities, individual sectors of society (such as health or environmental sectors), and society as a whole. For example, to promote the health of lower-income clients, you can help them access resources and supports that will enhance their personal skills. Community programs such as school lunch programs, recreational activities, collective kitchens, and support groups can be provided. You can lobby government sectors responsible for housing and employment to implement healthy public policies pertaining to affordable housing, job creation, child care, income security, and financially accessible health services. On a societal level, nurses can raise awareness about the negative effects of poverty on health and well-being and can advocate for policies that will decrease poverty. The population health promotion model shows how evidence-informed decision making is a foundation to ensure that policies and programs focus on the right issues, take effective action, and produce successful results (Hamilton & Bhatti, 1996), the "why" of action (Saskatchewan Health, Population Health Branch, 2002). Evidence is informed by research, experiential learning, and evaluation of programs, policies, and projects. Values and assumptions that are the foundation of the model include the following:

- Stakeholders representing the various determinants must collaborate to address health determinants.
- Society is responsible for its members' health status.
- Health status is a result of people's health practices and their social and physical environments.
- Opportunities for healthy living are based on social justice, equity, and relationships of mutual trust and caring, rather than on power and status.
- Health care, health protection, and disease prevention complement health promotion.
- Active participation in policies and programs is essential.

Summary

This chapter has introduced you to different ways of viewing health and health determinants, including the historical development of these concepts within the Canadian context. The content of the chapter challenges you to approach health situations broadly by identifying the myriad determinants that influence health. An increased understanding of health determinants should enable you to provide more sensitive care at the individual level and to consider strategies at the community and policy levels that will address the root causes of health situations.

❖ KEY CONCEPTS

- Health conceptualizations and determinants influence the nature and scope of professional practice.
- Definitions of health can be classified in several ways; recent definitions reflect a multidimensional perspective and a positive orientation.

- Three recent approaches to health are medical, behavioural, and socioenvironmental.
- Behavioural approaches focus primarily on health practices.
- Socioenvironmental approaches emphasize psychosocial factors and socioenvironmental conditions.
- Health determinants are interrelated.
- Canada is a leader in ever-changing views of health and health determinants.
- Health promotion differs from disease prevention.
- Three levels of disease prevention are primary (protection against disease), secondary (activities that promote early detection), and tertiary (activities directed toward minimizing disability from disease and helping clients learn to live productively with their limitations).
- The *Ottawa Charter* identifies five major categories of health promotion strategies: building healthy public policies; creating supportive environments; strengthening community action; developing personal skills; and reorienting health care services.

❖ CRITICAL THINKING EXERCISES

1. Describe your current level of health. What criteria did you use? Which definition of health discussed in this chapter best matches your understanding of health? Consider another definition of health discussed in this chapter. Does your current level of health change on the basis of this definition? How might your nursing practice differ depending on which conceptualization of health you choose to guide your practice? How might your definition of health change as you experience different life transitions (e.g., aging, parenthood)?
2. What do you consider to be the three most important health problems facing Canadians today? What are the major determinants of these problems? Which health promotion strategies would you consider the most appropriate to address them?
3. Imagine you are a community health nurse working in an area where many low-income women smoke. In a socioenvironmental approach to health, what questions would you need to address to decrease smoking behaviour in your area? How would your approach differ if you were using a behavioural approach to health?

❖ REVIEW QUESTIONS

1. The *Lalonde Report* is significant in that it was the first to emphasize
 1. A behavioural approach to health
 2. A medical approach to health
 3. A socioenvironmental approach to health
 4. Physiological risk factors
2. The "watershed" document that marked the shift from a life-style to a socioenvironmental approach to health was the
 1. Lalonde Report
 2. Adelaide Statement on Health in All Policies
 3. Toronto Charter
 4. Ottawa Charter
3. From a socioenvironmental perspective, the major determinants of health are
 1. Psychosocial risk factors and socioenvironmental risk conditions
 2. Physiological risk factors and behavioural risk factors
 3. Behavioural and psychosocial risk factors
 4. Behavioural and socioenvironmental risk factors

4. The main reason that intersectoral collaboration is a necessary strategy to reach the goal of "Health for All" is
 1. The determinants of health are broad
 2. Intersectoral collaboration is cost-effective
 3. Intersectoral collaboration encourages problem solving at a local level
 4. Intersectoral collaboration is less likely to result in conflict
5. Providing immunizations against measles is an example of
 1. Health promotion
 2. Primary prevention
 3. Secondary prevention
 4. Tertiary prevention
6. Which one of the following statements does *not* accurately characterize health promotion?
 1. Health promotion addresses health issues within the context of the social, economic, and political environment.
 2. Health promotion emphasizes empowerment.
 3. Health promotion strategies focus primarily on helping people develop healthy behaviours.
 4. Health promotion is political.
7. The belief that health is primarily an individual responsibility is most congruent with the _____ approach to health.
 1. Medical
 2. Behavioural
 3. Socioenvironmental
 4. Critical/structural
8. All of the following statements accurately describe the Population Health Promotion Model *except*
 1. The model suggests that action can address the full range of health determinants
 2. The model incorporates the health promotion strategies of the *Ottawa Charter*
 3. The model focuses primarily on interventions at the societal level
 4. The model attempts to integrate population health and health promotion concepts
9. Which of the following is the most influential health determinant?
 1. Personal health practices
 2. Income and social status
 3. Health care services
 4. Physical environment

10. Health promotion activities are aimed at
 1. Providing protection against disease
 2. Increasing the level of well-being
 3. Avoiding injury or illness
 4. Teaching clients to learn to live with their limitations

Rationales for the Review Questions appear at the end of the book.

The Canadian Health Care Delivery System

Written by Pammla Lusenga Petrucka, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms.
- Discuss the evolution of Canada's social safety net and Medicare.
- Identify and define the principles of the *Canada Health Act* and significant legislations related to the Canadian health care system.
- Discuss principal factors influencing health care reform and the current health care delivery system.
- Discuss patients' rights to health care.
- Discuss multiple roles and challenges for all categories of regulated nurses in different health care settings.
- Describe five levels of health care and associated types of services.
- Identify various settings and models of care delivery in the Canadian health care delivery system.
- Identify initiatives related to enhancing quality of the Canadian health care delivery system.

Nurses are an essential part of the Canadian health care delivery system, constituting the largest group of human health resources and recognized as invaluable to the health of Canadians. Nursing services are necessary for virtually every patient seeking care. In 2009, there were 284,690 registered nurses (RNs), including 2048 nurse practitioners (NPs), in Canada (76.4% of the regulated nursing workforce), 85,277 (22.1 %) licensed practical nurses (LPNs), and 5321 (1.5%) registered psychiatric nurses (RPNs), reflecting an overall increase of 1.3% since 2005 (Canadian Institute for Health Information [CIHI], 2010a; Canadian Nurses Association [CNA], 2011) (Box 2-1).

Since the late 1990s, the Canadian nursing workforce size has remained relatively stable. Canada has 88.2 regulated nurses per 10,000 population, compared to 100.3 in the United Kingdom and 105.0 in the United States (CIHI, 2010a). *Building the Future* (2006) was the first national

► BOX 2-1 Facts About Nursing in Canada, 2009

- For RNs, 62.6% practised in the hospital sector; 9.9%, in long-term care; 14.2%, in community and home care; and 13.3%, in other settings.
- For LPNs, 45.6% practised in hospitals; 7.8% in the community; and 39.8% in long-term care.
- For RNs, 36.7% were degree-prepared; 23.7% were baccalaureate prepared on entry to practice.
- Foreign-graduate representation in the regulated nursing work force included 8.3% of the RNs; 2.3% of LPNs; 7.8% of RPNs.
- 15,603 RNs obtained certification through the CNA program in one of eighteen specialty areas.
- In 2008, the ratio of regulated nurses employed in Canada was one RN for every 127 persons and one LPN for every 439 persons.
- The ratio of NPs employed in Canada was one NP for every 16,945 persons.
- By gender, for RNs and NPs, 94% were female and 6% were male; for LPNs, 93% were female and 7% were male.
- Average age of RNs was 45.1; of LPNs was 43.4; and of RPNs was 47.6.
- For RNs, 23.3% were aged 55 years or older; 9.7% were aged 60 years or older; and 2.3% were aged 65 years or older. For LPNs, 26.7% were aged 55 or older; 8% were aged 60 or older.

study endorsed by stakeholder groups to outline a long-term strategy to ensure adequate Canadian nursing human resources. Currently, the nursing workforce is challenged by aging workers, high retirement rates, ethical international recruitment, and lack of full-time positions.

Nursing is integral to the health care delivery system, so understanding the system and the issues that affect how care is provided is imperative. As a practising nurse, you must appreciate the complexities of a health care delivery system replete with human and fiscal resource challenges and imperatives for quality services. Financial pressures have forced hospitals and other institutions to shift priorities and to control costs by cutting the workforce and support services. Nurses can help restructure delivery systems and contribute to the achievement of excellence in health care. The success of health care depends on the participation of nurses to create health care systems that deliver quality, cost-effective care. Nurses must lead the way, advocating, reinforcing, and retaining the values of safe, quality, ethical, and evidence-informed patient care.

Evolution of the Canadian Health Care System

Despite significant changes since the 1960s, a network of national, provincial, and territorial social programs, referred to as the **social safety net**, is still needed to protect the most vulnerable members of Canadian society. Most programs are targeted to specific populations (e.g., older adults, children), but a few are universally accessible to all Canadians. For example, provincial social assistance programs provide income support to individuals who are unemployed or underemployed for long periods of time, and the federal Employment

► BOX 2-2 Moments in Canadian Nursing History*

Throughout Canada's history, nurses have been meeting the health care needs of individuals, families, and communities. As nurses encountered changing practice environments, such as world wars or the Great Depression in the 1930s, they transformed their practices and skills to meet the new situations. During English–French hostilities from 1756 to 1760, the Grey Nuns cared for sick and wounded soldiers, including British prisoners of war. This order was known for its excellent hospitals, offering care regardless of race, colour, creed, or financial status. By the middle of the twentieth century, nursing transformed from a predominately spiritual vocation to a secular profession (Mansell, 2004). Most nurses worked in hospitals and communities but were also present in nursing and health care organizations such as the Red Cross, the Victorian Order of Nurses (VON), military or navy service, tuberculosis sanatoria, professional nursing associations, and nursing unions. Although “the practice of nursing is perceived as an integral part of health care services in Canada” (Mansell, 2004, p. 204), the struggle for professionalism and recognition has not been an easy one.

*Section contributor: S. L. Bassendowski, RN, EdD

Insurance program provides income support for those with short-term employment interruption. A key component of Canada's social safety net is the provision of hospital and medical insurance, known as **Medicare**, which is funded by general taxation.

Although referred to as a “national” program, Medicare is, in fact, an interlocking set of 10 provincial and three territorial insurance schemes that provide “prepaid” access to medically necessary hospital and physician services to all citizens and permanent residents (Health Canada, 2010a). Medicare is a source of national pride as a Canadian commitment to the well-being of its citizens, as well as a source of national debate regarding costs, effectiveness, and sustainability. Sustainability considers long-term maintenance and invokes creation of “standards of health human resources, infrastructure, clinical outcomes and fiscal capacity” for the health system (Kondro, 2010). Few issues are as important, controversial, and a source of solidarity for Canadians as health care.

Early Health Care in Canada

Europeans who came to Canada in the fifteenth century brought infectious diseases that flourished under conditions of poor sanitation. Settlements enacted public health laws to control the spread of diseases. For years, government care was limited to essential services (e.g., care of insane persons, epidemics). Permanent boards of health did not exist; families, churches, and local communities were expected to be self-reliant in handling other medical and social problems. The trials, stories, and efforts of these first Canadian nurses were legendary (Box 2-2).

Canada became a self-governing colony with the passage of the *British North America Act* (also known as the *Constitution Act*) in 1867, which united three colonies into the original four provinces of Ontario, Quebec, Nova Scotia, and New Brunswick. This Act accorded certain powers to the national (federal) and provincial governments. Responsibility for health, education, and social services was accorded to the provinces; the federal government retained jurisdiction for parts of these

Figure 2-1 Military nurses. **Source:** Photo courtesy of WJR Bateman.

public policies (Storch, 2006). Health care for Canada's Aboriginal peoples and pharmaceutical safety remain federal responsibilities, but regulation of hospitals is a provincial jurisdiction.

As Canada's population grew and became more urban and industrial, crowded living conditions, poor housing, and poor sanitation led to more disease. Provinces enacted public health acts to establish local boards of health to hire medical health officers and sanitation inspectors. The nurses working directly in the community and with the poor were the first public health nurses.

By 1920, health and social programs had expanded, and voluntary agencies formed; the latter included the Children's Aid Society (formed in 1891), the Red Cross (in 1896), the Victorian Order of Nurses (in 1897), and the Canadian Mental Health Association (in 1918). Municipalities organized services for the poor and established hospitals. Patients who could not pay depended on charity (Figure 2-1). Fraternal societies (e.g., Knights of Columbus) and unions created trusts that members could access when ill, injured at work, or unemployed. Such programs were precursors of modern employment insurance.

As urbanization continued, rural communities had difficulty attracting and paying physicians. The federal *Municipality Act* of 1916 gave communities the power to levy taxes to pay for physicians. The Great Depression dramatically affected the health care system as many could not pay medical bills, and hospital stays caused financial ruin. As needs increased, it became apparent that many provinces did not have the tax base to fund these services and to ensure parallel services across the country.

These hardships inspired the Canadian provincial governments to create a prepaid medical and hospitalization insurance plan. In 1947, Premier Tommy Douglas of Saskatchewan introduced a public, universal hospital insurance plan, which became the basis of the first major federal initiative for national hospital insurance and led to the *Hospital Insurance and Diagnostic Services Act (HIDSA)* of 1957. For provinces establishing universal hospital insurance, *HIDSA* provided federal funds to cover approximately half of service costs. By 1961, all provinces and territories were providing coverage for **inpatient** hospital care.

To ensure medical services outside of hospitals, Saskatchewan again took the lead. With federal government funding for half of the hospital insurance, Saskatchewan could afford to provide medical insurance and, in 1962, passed the *Medical Care Insurance Act*. The legislation was opposed by the province's physicians, who went on a 23-day strike, after which they reached a compromise in which the physicians' autonomy to practise was preserved in exchange for agreeing to a single-payer insurance system to fund their services.

In 1964, the Royal Commission on Health Services (RCHS) was appointed to study the provision of hospital and medical care to all Canadians and concluded that "strong federal government leadership and financial support for medical care" was needed (Wilson, 1995). The *Hall Commission Report*, named after lead commissioner Justice Emmett Hall, called for national expansion of the Saskatchewan model on a cost-shared basis similar to *HIDSA* (RCHS, 1964, 1965).

Based on these recommendations, the federal government passed the *Medical Care Act* of 1966. Federal grants were awarded on a cost-sharing basis with the provinces if programs met certain criteria for coverage of hospital and physician services. Federal, provincial, and territorial governments agreed to share health care expenses equally. By 1972, all provincial and territorial insurance plans extended coverage to include medical services provided outside hospitals. Thus began modern Medicare, as all Canadians had free access to hospital and medical care, regardless of personal wealth.

Although programs prospered, cost sharing did not last. In 1977, the Canadian government enacted the *Federal Provincial Fiscal Arrangements and Established Programs Financing Act* to replace cost sharing with block transfers of funds and a complicated formula of transferring tax points from the federal government to the provinces and territories. These block transfers resulted in decreased federal contributions. To address this shortfall, some provinces allowed extra billing of patients by hospitals and provider groups over the amount that the universal insurance program covered. Medicare's defenders saw these charges as a threat to the universality of Canada's medical insurance scheme and in violation of the principle that care should be accessible on the basis of need and not on ability to pay.

The federal government's response was to enact the *Canada Health Act* in 1984, which amalgamated the previous acts of *HIDSA* and *Medical Care Act* and effectively banned extra billing and user fees. The *Canada Health Act* added the principle of **accessibility** to the principles of **public administration**, **comprehensiveness**, **universality**, and **portability** (Table 2-1). Recently, a sixth principle—**sustainability**—has been debated. These principles apply to all **insured residents** (i.e., eligible residents), but exclude members of the Canadian Forces, Royal Canadian Mounted Police (RCMP), veterans, and inmates of federal penitentiaries. First Nations and Inuit health services receive special considerations, discussed later in this chapter. Under previous Acts, access to services was through physician gatekeepers, but this revision to the *Canada Health Act* allowed multiple points of access and insurance through additional care providers. Despite opposition, all provinces and territories were following *Canada Health Act* principles by 1987 in pursuit of its primary objective "to protect, promote and restore the physical and mental well-being of residents of Canada and to facilitate reasonable access to health services without financial or other barriers" (Health Canada, 1992, 2010b).

► TABLE 2-1

Principles of the Canada Health Act of 1984

Public administration	A public authority administers and operates the plan on a nonprofit basis; responsible to the provincial and territorial governments for decision making on benefit levels and services; subject to financial audits.
Comprehensiveness	Covers all medically necessary hospital and physician services; as the province or territory permits, services of other health care practitioners. Palette of publicly funded services for each province and territory varies, which is controversial (Commission on the Future of Health Care in Canada (CFHC) [Romanow, 2002]).
Universality	Insured residents entitled to health care services provided by the plan on uniform terms and conditions. Universality negates discrimination based on race, gender, income, ethnicity, or religion (Romanow, 2002).
Portability	Insured residents can access health care services in another province or territory without cost or penalty. Personal coverage must be maintained when an insured person moves or travels within Canada or travels outside of Canada.
Accessibility	Insured residents have reasonable access to health care facilities and providers; additional charges for insured services are not permitted; essential health care services must be available to all Canadians on the basis of need (Romanow, 2002).

Based on Health Canada. (2010). *Canada's health care system (Canada Health Act)*. Retrieved from http://www.health.gov.bc.ca/library/publications/year/2007/conversation_on_health/PartII/PartII_HealthAct.pdf.

The *Canada Health Act* is a major piece of legislation influencing the delivery of health care services across Canada. Other federal legislation (Table 2-2) influences health and health services for Canadians in areas such as tobacco use, environmental health, and health research.

Aboriginal Health Care

The major legislation is the *Indian Act* of 1985 (see <http://laws.justice.gc.ca/en/I-5/>), which identifies the federal government's role in providing health care services to First Nations and Inuit people. First Nations and Inuit Health, part of Health Canada, and Indian and Northern Affairs Canada share responsibility for ensuring health care services are provided to Canada's First Nations and Inuit people (Health Canada, 2011; Indian and Northern Affairs Canada, 2010a). Treaties with so-called Indian bands in Canada were signed before Confederation with the British government and after Confederation with the Government of Canada (Natural Resources Canada, 2003). These treaties outlined agreements regarding land, services, and relationships; some (such as Treaty 6) included a provision for health care services to be provided to the First Nations communities, often referred to as the "medicine chest" clause (Indian and Northern Affairs Canada, 2010a). These treaties enable direct delivery of services to First Nations and Inuit peoples, regardless of where they live in Canada, including **primary health care (PHC)** and emergency services on remote and isolated reserves where provincial or territorial services are not readily available; community-based health programs both on reserves and in Inuit communities; and non-insured health benefits programs (e.g., pharmaceuticals, dental, vision, and medical transportation). All four levels of government (federal, provincial and territorial, and Aboriginal) are working together to improve and integrate health service delivery, with anticipated allocations for 2011–12 at \$1977.6 million and an 1862-full-time-equivalents workforce (Treasury Board Secretariat, 2009).

Aboriginal self-governance has been enabled through the "inherent right of self-government" under Section 35 of the *Canadian Constitution Act* of 1982. As self-governance models emerge, health care, as part of the services and programs palette within Aboriginal jurisdiction, will challenge health

Purpose

Regulates pollution prevention; environmental protection and human health contribute to sustainable development
 Strategizes and funds health-related research through 13 virtual institutes
 Controls certain drugs, their precursors, and related substances
 Develops and implements civil emergency plans; facilitates and coordinates across government levels and institutions, foreign governments, and international organizations
 Regulates food, drugs, cosmetics, and therapeutic devices
 Controls introduction and spread of infectious or contagious diseases
 Regulates manufacture, sale, labelling, and promotion of tobacco products

*Section contributor: T. McIntosh, PhD

care professionals to be “responsive to [Aboriginal] political, economic, legal, historical, cultural and social circumstances” (Indian and Northern Affairs Canada, 2010b).

Organization and Governance of Health Care

Under the *Canadian Constitution Act*, administration and delivery of health care services are primarily provincial or territorial responsibilities. The federal government has a role in health care financing, enforcement of the *Canada Health Act*, delivery of services to previously described targeted groups, and setting national agendas such as those relating to public health and safety, pharmaceuticals, and biomedical and health services research.

Federal Jurisdiction

The federal government is charged to do the following:

- Set and administer *Canada Health Act* principles for the health care system
- Assist in financing provincial and territorial health care services through transfer payments (i.e., transferring tax money to share cost) in alignment with *Canada Health Act* principles
- Deliver or co-deliver health services for targeted groups, as described previously
- Provide national policy and programming to promote health and prevent disease, such as healthy environment, consumer safety, and public health programs

Provincial and Territorial Jurisdiction

Each provincial and territorial government is charged to do the following:

- Develop and administer its own health care insurance plan
- Manage, finance, and plan insurable health care services and delivery, complying with *Canada Health Act* principles (Table 2-1)
- Determine organization and location of health care facilities, mix of health care providers employed in these facilities, and money allocations for health care services
- Reimburse physician and hospital expenses; provide some **rehabilitation** and long-term care services, usually on the basis of co-payments with individual users.

Each provincial and territorial plan is unique; what is covered and by how much varies across the country. For example, coverage for drugs taken outside of hospitals, ambulance services, and home care varies widely by province and territory. Marchildon (2006) reviewed what is and is not covered by each province and territory. To offset costs for services not covered by provincial or territorial insurance, Canadians can buy private health insurance or participate in employer-offered individual or group insurance plans.

Professional Jurisdiction

Most health professions (i.e., medicine, nursing, pharmacology) in Canada are self-regulated, which means they determine standards, competencies, codes of ethics, and disciplinary actions for their respective members. Some professions are regulated through governments (e.g., emergency medical technicians Ontario) or other regulatory mechanisms (e.g., osteopathic physicians in British Columbia). In some cases, so-called omnibus legislations regulate several professions simultaneously (e.g., Alberta's *Health Disciplines Act* of 2000).

Health Care Spending

“Canadians pay, directly or indirectly, for every aspect of our health care system through a combination of taxes, payments to government, private insurance premiums, and direct out-of-pocket fees of varying types and amounts” (Romanow, 2002, p. 24). In 2010, private health care spending represented 14.8% of the total health care costs through out-of-pocket payments (eighth highest among Organization for Economic Cooperation and Development [OECD] countries); another 12.8% was covered by private insurance programs (OECD, 2010). The average Canadian household expended \$2044 on health care (up 4.5% from the previous year), with a total spending per person varying by province, the highest being in Alberta (\$6266) and the lowest in Quebec (\$5096) (CIHI, 2010b).

In 2010, total spending on health care is expected to reach \$191.6 billion (\$135.1 billion government spending, \$56.5 billion private spending); 5.2% more than the previous year, but maintaining approximately a 70–30 split (CIHI, 2010b). Overall, in Canada, \$5614 per person was spent on health care in 2010, in comparison with \$4548 in 2006 (CIHI, 2010b). Furthermore, in 2009, trends showed higher per capita spending for infants (at \$8239) and older adults (ranging from \$5539 [age 65–69] to \$17,469 [over 80]) than for younger adults (cbcnews.ca, November 19, 2009). Although older adults constitute less than 14% of the population, they account for approximately 44% of government health care spending (CIHI, 2010b).

Internationally, in 2008, Canada was ranked fifth (\$4063 US per person) for health care spending compared to the first-ranking United States (\$7538 per person) (CIHI, 2010b).

According to CIHI (2010b), hospital and health care institutions (29%), retail drug sales (16%), and physician services (14%) account for nearly 60% of health care spending. For 2010, estimated health expenditures forecast hospitals at \$55.3 billion, pharmaceuticals at \$31.1 billion, and physician services at \$26.3 billion. Despite these significant expenditures, Canada ranks tenth of 16 OECD countries (Conference Board of Canada, 2009) on quality indicators such as life expectancy, self-reported health status, disease-specific mortality rates, lifestyle behaviours (e.g., smoking, obesity), and mortality due to medical misadventure.

Trends and Reforms in Canada's Health Care System

Since the 1980s, rapid changes in health care delivery, technologies, and public expectations have challenged the Canadian federal, provincial, and territorial governments to reconstruct a health care system that balances current and future political, legal, economic, and social realities (Petrucka, 2005). In most provinces, restructuring has become entrusted to **regional health authorities**, which are led by appointed or elected community representatives and whose mandates, roles, and responsibilities are provincially legislated (Lewis & Kouri, 2004). Regionalization was intended to streamline health services, to reduce fragmentation, to respond to local needs, to improve public participation, and to address the continuum of health care services from disease prevention and health promotion to curative, supportive, restorative, and palliative treatments (Lewis & Kouri, 2004). Although these principles were initially attractive and promising, the process has not lived up to its potential; instead, it has become primarily

a fiscal exercise rather than a philosophical or health-motivated reform (Petrucka, 2005).

According to Armstrong (1999), health reform primarily concerns continuity and integration, quality and accountability, and disease prevention and health promotion. Framed within the determinants of health, reforms are intended to deliver better quality and appropriate care at lower cost by adopting sound business and managerial strategies. Two influential national reports on Canada's health care system reforms are *The Kirby Report* (Kirby, 2002) and Romanow's Commission on the Future of Health Care in Canada (CFHC) (2002) (Box 2-3).

In 2004, the federal government initiated a transfer scheme (i.e., the *10-Year Plan to Strengthen Health Care*) to increase the efficiency and sustainability of the Canadian health care system (CGA-Canada, 2010). This plan, which is contributing to a

dialogue on promising practices and concerns on future directions, expires in 2014.

Because health care costs are rising faster than government revenues, some Canadian citizens and decision makers believe that health care spending will eventually crowd out spending on other programs in the social safety net and consume 100% of all monies (MacKinnon, 2004). If health care spending absorbs all available monies, the future of education programs, social services, transportation safety, and environmental protection—which have a profound impact on health—is uncertain.

The CNA (2009) continues to advocate for a publicly funded, not-for-profit health care system rooted in the principles of the *Canada Health Act* and advancing nursing as a primary access point to health care.

► BOX 2-3 Influential Health Care Reports

The Romanow Commission

Romanow (2002) concluded that Medicare is sustainable and must be preserved because it represents Canadians' core values. He emphasized modernizing the *Canada Health Act* through appropriate funding and the following changes:

- Create a new diagnostic service fund
- Build information technology infrastructure
- Improve access (e.g., in rural and remote areas, for Aboriginal peoples)
- Ensure and measure quality
- Improve and expand PHC
- Strengthen and expand home care
- Offer catastrophic drug coverage
- Create a national health council responsible for indicators and performance measures

Romanow (2002) stressed accountability for funding and services provided.

The Kirby Report

Kirby (2002) concluded that the current Medicare system is not sustainable and advocated for stronger private sector involvement in health care delivery. Although Kirby did not address the core values or recommend changes to the *Canada Health Act*, he clarified the impact of spiralling health care costs on other social programs. Kirby recommended the following:

- Shifting funding for hospitals to a service-based model
- Granting more responsibility to regional health authorities for delivering publicly insured health services, contracting out these services, or both
- Reforming PHC
- Offering a health care guarantee to Canadians (e.g., time limits for wait times; if exceeded, the government pays for care provided elsewhere)

Like Romanow, Kirby (2002) emphasized accountability for funding and services, but instead of a national health council suggested an appointed council with limited advisory functions.

Role of Nurses in Health Care Policy

Nurses play a key role in health care policy, both as leaders at the political and community levels and in their everyday work lives. Individually and collectively, nurses are integral to policy development (Falk-Raphael, 2005; Hart, 2004). Health care needs a coordinated, integrated approach by nurses if they are to inform policy decisions and help shape the country's health care systems (Villeneuve & MacDonald, 2006). Almost continually since the late 1950s, the position of a senior or chief nurse has existed at the federal government level (in the Federal Office of Nursing Policy), and many provincial governments employ nurses in similar positions. These nurses bring nursing perspectives to health policy decisions, present government perspectives to nurses and patients, and articulate the potential impact of policy decisions to politicians and other stakeholders. For example, the Federal Office of Nursing Policy is charged with health policy and program development across Health Canada through evidence-informed nursing perspectives.

Right to Health Care

The consensus in Canada is that everyone has a right to health care. In general, consumers have a right to determine what kind of health care should be available to them. The *Canadian Charter of Rights and Freedoms* of 1982 does not explicitly include health care as a right; therefore, federal and provincial legislation must prove legal entitlement. (Only Quebec has health care rights in its legislation.) The *Canada Health Act* influences rights by setting conditions for federal health care co-funding, but the right to health care itself is not guaranteed in the Act.

Rights Within the Health Care System

Sutherland and Fulton (1992) articulated rights that Canadian health care workers expect: namely, the right to reasonable working conditions, including safety and absence of discrimination. Professional associations and unions work to establish and protect the rights of health care workers. Romanow (2002) called for the adoption of a health covenant that would specify the rights, obligations, and expectations of governments, citizens, and health care professionals. According to the Canadian Healthcare Association (CHA) (2010), no national or provincial patient charters of rights exist; however, the Consumers' Association of Canada and the Ontario Hospital Association have advanced such documents. Ontario's Assistant Deputy Minister of Health and Long-term Care stated that "creation of a patient-centred charter for quality in health care would provide

clarity on what needs to be fixed about Canada's health care system" (Collier, 2010). Saskatchewan's independent *Patient First Review* resulted in a key recommendation to "make patient- and family-centred care the foundation and principal aim of the Saskatchewan health system . . . as an overarching guide for health care organizations, professional groups and others to make the Patient First philosophy a reality in all work places" (Dagnone, 2009).

Although, in practice, no statutory requirement exists in Canada to include patient advocacy groups in the policymaking process, a number of national groups (e.g., Canadian Cancer Society), as well as disease-specific patient groups, are involved. These groups share information, endorse, report on, or criticize health care policy decisions (Health Consumer Powerhouse AB & Frontier Centre for Public Policy, 2008).

Primary Health Care

Primary health care (PHC) is a foundation of Canada's health care system, providing an entry point of contact into the health care system, as well as the vehicle for **continuity of care** (Health Council of Canada [HCC], 2008). (See Chapter 17 for more on continuity of care.) Health systems based on PHC are more effective and efficient than those centred on specialty and tertiary care (Starfield et al., 2005). Rooted in a 1974 document by then-Minister of Health and Welfare, Marc Lalonde, PHC was envisioned as addressing nonmedical determinants of health to improve health (HCC, 2005). The report outlined the connection between health status and social determinants of health, including employment, poverty, lifestyle, environment, and genetic endowment. Other documents, such as the *Alma-Ata Declaration on PHC* (World Health Organization [WHO], 1978) and the *Ottawa Charter for Health Promotion* (Charter) (Lalonde, 1986), built the framework that has informed population health and health promotion approaches globally. The Canadian federal, provincial, and territorial health departments have established units or branches that focus on, promote, and fund PHC-based programs and services.

PHC is a philosophy and model for improving health that supports essential health care services, with a strong emphasis on the principles of health promotion and disease prevention. Most definitions of PHC recognize the importance of emphasizing the determinants of health and strategies to advance individual and population health (HCC, 2008).

PHC, as an integrated approach, builds a related spectrum of programs and services external to the traditional health care system. This palette embodies health in its broadest sense, such as income, housing, education, and environment (Health Canada, 2006). The PHC model (Figure 2-2) focuses on collaboration among health professionals, community members, and others working intersectorally, emphasizing health promotion, development of health policies, and prevention of diseases for all. According to the National Primary Health Care Awareness Strategy (NPHCAS) (2006b), PHC does the following:

- Prevents people from becoming ill or injured
- Enables self-care
- Optimizes health care provider expertise
- Enables health care workers to treat acute and episodic illness
- Coordinates for efficiency and access
- Enables individuals to participate fully in their health care
- Recognizes factors external to the health care system that affect individual and community health

Figure 2-2 Primary health care model: A multisectoral or intersectoral approach. **Source:** From Shoulz, J., & Hatcher, P. A. (1997). Looking beyond primary health care: An approach to community-based action. *Nursing Outlook*, 45(1), 24. © 1996 by P. Hatcher, J. Shoulz, and W. Patrick.

Throughout this book, "Focus on Primary Health Care" boxes highlight the vital role that nurses play in providing PHC. Box 2-4 links health care situations to PHC principles.

Barriers to Primary Health Care

The meaning of PHC has caused confusion among health care consumers and even health care providers. The distinction between PHC and **primary care (PC)** is difficult to understand. PC focuses on personal health services, whereas PHC extends beyond PC to include health education, nutrition, maternal and child health care, family planning, immunizations, and control of locally endemic diseases. This broader concept of PHC proposed for Canada relates to the continuum of care by interprofessional teams of providers working with the patient as the driver (Annapolis Valley Health, 2007). Some professionals do not support a PHC model, which requires interdisciplinary collaboration and flexible boundaries between health care professions. In response, Health Canada (2010c) introduced the Interprofessional Education for Collaborative Patient-Centred Practice strategy, providing opportunities across Canada for improving socialization, decision making, respect, understanding, and competencies related to enhancing collaborative practice, which potentially yields greater provider satisfaction, enhanced recruitment and retention, and improved patient safety and outcomes.

Challenging the adoption of PHC is an underlying concern as "many Canadians see the health system as an 'illness care' system that will be there when they need it" (CNA, 2003). Some experts fear that if monies are dedicated to PHC priorities and implementation, benefits will be limited, at least in the near term. PHC is a sensible approach to health care that is cost-effective and benefits most people. For example, by

BOX 2-4 FOCUS ON PRIMARY HEALTH CARE

The Four Pillars of Primary Health Care*

A number of models for PHC exist, such as the NPHCAS (2006a) model, describing four pillars of PHC as teams, access, information, and healthy living.

Teams

PHC functions with team-based care, which improves access and coordination, reduces waiting times, and enhances comprehensiveness of care (Barrett, Curran, Glynn, & Godwin, 2007). A good team works together to solve or explore common issues, with the best possible participation of the patient (HCC, 2009). Despite knowledge that effective PHC represents a promising path to improving the comprehensiveness of health care, there has been minimal progress in the formation of such teams (e.g., by March 2009, 31% of Saskatchewan's population was served by PHC teams) (Dagnone, 2009).

West Winds Primary Health Centre (WWPHC) in Saskatoon is a PHC centre addressing the health care needs of men, pregnant and non-pregnant women, adolescents, children, newcomers, Aboriginal peoples, and older adults. WWPHC functions in partnership with the University of Saskatchewan and Saskatoon Health Region to deliver community-based PHC and offer innovative research and program evaluation opportunities for health disciplines students.

Through transdisciplinary and intersectoral collaboration, WWPHC provides a full range of services that include but are not limited to health promotion, chronic disease prevention and management (i.e., diabetes education), mental health (including maternal) and addiction services, public health, foundational programs (Healthy Mother-Healthy Baby, Food for Thought), and dental clinics. The staff includes physicians, nutritionists, psychologists, nurses, NPs, therapists (i.e., occupational, physio), speech-language pathologists, pharmacists, social workers, and clinical researchers. A community participation working group and a collaborative practice resource group provide direction and support development of evidence-informed programs.

Access

In 2007, 16.7% of Canadians had difficulties in accessing routine or ongoing health care (CIHI, 2009a). PHC strives to ensure better access to appropriate services when and where they are needed by expediting entry into the health care system, maximizing scopes of practice for health professionals, and reducing demands for care by keeping clients healthier (Rachlis, 2005).

In urban settings, interprofessional teams work to bring PHC to the streets. They work with vulnerable groups—those in poor health (often with addictions, HIV/AIDS, hepatitis C), homeless, malnourished and/or lacking support—to assess and monitor health status and provide care “in place.” Nurses on “PHC street teams” care for individuals and

communities in need; for example, one nurse visits a 17-year-old prostitute who is 8 months pregnant, is addicted to crack, and lives within a boxcar community. He runs a community program called “Having Healthy Babies” for young, vulnerable women, co-located at a centre near the train tracks, thereby increasing accessibility. Also, he advocates for a “chili lunch” program through local church and business communities for “on-the-street” youth.

Information

In 2007, 17.1% of people reported difficulty in accessing health information on a continuous basis (CIHI, 2009a). Using technology to improve efficiency and quality is a critical part of health care renewal (HCC, 2008). Tools (e.g., electronic health record [EHR], diagnostic equipment) and skills (e.g., telehealth) facilitate quality, access, and coordination of information. One technology is telephone triage, which is used successfully in many jurisdictions; individuals dial a toll-free number to connect with a qualified nurse who can answer health questions. This technology addresses access to health care, especially in rural and remote areas. In 2009, Nova Scotia introduced HealthLink 811, with 29 RNs managing over 100,000 calls, resulting in over 40% of the callers being guided through self-care, rather than entering the health system (CBC News, August 3, 2010). Canada Health Infoway (CHI) is a federally funded, independent, not-for-profit organization with representation from 14 federal, provincial, and territorial health ministries. CHI fosters and accelerates the development and adoption of electronic health (e-health) information systems on a pan-Canadian level. CHI envisions a high-quality, sustainable, and effective info-structure to provide Canadians and health professionals with timely, appropriate, and secure access to information across the health care system, such as supporting triage nurses to monitor patient kiosks at the Scarborough Hospital (CHI, 2011).

Healthy Living

PHC embraces strategies of prevention, chronic illness management, and self-care, while recognizing that factors outside the health care system (e.g., social, economic, environmental) influence individual and community health.

An example is of a public health nurse in southern Ontario running a program that educated low-income mothers about nutrition, child development, and community action. The women shared strategies to meet their families' nutritional requirements on tight budgets. Upon learning that a national bakery was closing its local day-old-bread outlet, the nurse coached the women to call a local newspaper reporter, who, in turn, contacted the bakery's president and persuaded the owner to keep the outlet open. The nurse's health promotion activities resulted in a decision that benefited the community.

attending a community health program on infant and child care, parents learn the importance of recognizing signs and symptoms of urinary tract infection (UTI) in children and the importance of seeking medical treatment. With this knowledge comes prevention of long-term serious complications of untreated UTIs, such as kidney damage, and reduced health care costs.

Other potential barriers include lack of information about technology support, disincentives created by compensation systems, and lack of physician leadership and participation on PHC teams (Dagnone, 2009).

Future of Primary Health Care

Strengthening PHC will meet Canadians' needs for prompt access to comprehensive evidence-informed services (CIHI, 2009b). In a restructured health care system that emphasizes PHC, programs necessarily will cross sectors. For example, trauma programs will have health promotion activities (road safety education), preventive programming (helmet legislation), **secondary care** and **tertiary care** (emergency transportation), and rehabilitation (head injury–related recovery programs). Programs will cover multiple sites, may be defined

BOX 2-5 CASE STUDY

Primary Health Care

During a community meeting in a core area of a small city, parents, educators, health care professionals, and volunteers agreed to pilot an integrated program to reduce obesity in children. Social services staff and volunteers run a breakfast program. Fruits and vegetables for twice-daily snacks are donated by a local grocery store. Nutritionists and kinesiologists educate the teachers to integrate nutrition and physical fitness into the curriculum. Schools commit to having students and teachers participate in activities for at least 30 minutes every day and establish rules for school lunches (e.g., no soda pop). Nurse practitioners arrange visits with the parents of children identified as being overweight or at risk. If only 10% of the children in the program develop a healthier lifestyle, future savings to the health care system will pay for program costs.

by a particular disease or population group (e.g., children), and will comprise multiple disciplines and sectors of society (e.g., health care, education, justice systems). Nursing will have a significant role in every aspect of a PHC-integrated program.

More than three-quarters (76%) of Canadians reported the quality of PHC received in the previous 12 months was either “excellent” or “very good” (CIHI, 2009b).

Because of its integrated approach, PHC may hold the key to Canada’s looming health care crisis. If Canadians stay healthier because more money is spent on PHC, they will need less medical care, and the proportion of money going to medical care will decline. By integrating health care, education, social services, and the voluntary sectors, competition for government monies may decline and each sector will articulate beyond their own boundaries (Box 2-5). To promote the PHC agenda, resources and strategies to be considered are the following (HCC, 2005):

- Adequate, appropriate supply of human health resources
- A team approach focused on patient needs, collectively working to optimize outcomes
- Information technology (i.e., electronic health records)
- Governance and funding models supporting team-based care
- Links to public health
- A culture of accountability, performance measurement, and quality improvement

Settings for Health Care Delivery

Although health care delivery varies across Canada, three types of delivery agencies are comparable: institutional; community and voluntary; and private-sector agencies.

Institutional Sector

Institutional agencies including hospitals, long-term care facilities, psychiatric facilities, and rehabilitation centres offer health care services to inpatients (clients who stay at an institution for diagnosis, treatment, or rehabilitation). Most offer services to **outpatients** (clients who visit an institution for these services).

Hospitals. Hospitals have traditionally been considered major health care agencies, most specializing in **acute care** services. Acute care is health care delivered for a short time (usually days to weeks, typically less than three months) in

which an immediate health problem is diagnosed, treated, or both. Hospital services may include emergency and diagnostic, inpatient, surgical intervention, intensive care, outpatient, and rehabilitation services. The numbers of hospitals, hospital beds, and admissions in Canada have decreased significantly since the 1990s, creating pressures in dealing with the clients who have more acute and specialized needs. In 2007, Canada had 2.7 acute beds per 1000 population, mirroring the United States, but significantly lower than Australia’s 3.5 beds and Japan’s 8.2 beds (OECD, 2009). Hospitals strive to provide the highest quality of care possible with the newest treatments and technologies and to facilitate appropriate, safe, and timely patient discharge to the home, community, or a facility to manage remaining health care needs.

Hospitals are distinguished by their size (e.g., community hospitals), service provision (e.g., cancer care hospitals), and connection to academic institutions (e.g., university health science centres), as well as by public or private status. Public hospitals are financed and operated by a government agency at the local, provincial, or national level and constitute the largest group of health employers in Canada. Private hospitals are owned and operated by groups such as churches, corporations, and charitable organizations. Military hospitals, although limited in Canada, provide medical services to members of the military and their families. Veterans’ hospitals provide residential care, extended care, and rehabilitation to aging, injured, and disabled military veterans.

Roles and functions of hospitals and hospital-based nurses have evolved in this era of health care reform. Hospital nurses use critical thinking skills (see Chapter 11), apply the nursing process (see Chapter 12), coordinate and delegate care elements (see Chapter 10), and stress patient teaching and post-discharge self-care (see Chapter 20). An emerging trend is toward evidence-informed practice when patient interventions are determined. Nurses participate in discharge planning as a critical interdisciplinary coordination strategy in the continuity of care for clients, facilitating smooth and safe transitions of clients between levels of care and the community. Many hospital nurses specialize as clinical nurse specialists, caring for clients with specific needs (e.g., palliative) or specific diseases (e.g., cardiovascular). Other hospital roles include nurse manager, infection control coordinator, clinical educator, and clinical nurse researcher.

Long-Term Care (LTC) Facilities. LTC (extended care) facilities provide accommodations and 24-hour intermediate and custodial care (e.g., nursing, rehabilitation, dietary, recreational, social, and spiritual services) for residents of any age with chronic or debilitating illnesses or disabilities. Most residents are frail, older adults with multiple health issues (see Chapter 24). Some are younger adults with severe, chronic health conditions (see Chapter 23). LTC facilities function as the resident’s temporary or permanent home; therefore, the surroundings are as homelike as possible. The philosophy of care is to provide a planned, systematic, and interdisciplinary approach that helps residents reach and maintain their highest level of function. LTC facilities are not part of the insured services bundle within the *Canada Health Act*, although many provincial and territorial plans do provide some coverage. In these settings, nurses plan and coordinate resident care, manage chronic illnesses, and conduct rehabilitation programs and assume roles in education (see Chapter 20), communication (see Chapter 17), and family-related interventions (see Chapter 19).

Psychiatric Facilities. Located in hospitals, independent outpatient clinics, or mental health clinics, psychiatric facilities offer inpatient and outpatient services. Mental health is often seen as one of the “orphan children of Medicare,” never being fully integrated into the health care system (Romanow, 2002). Nurses in these facilities collaborate with doctors, psychologists, social workers, and therapists to make plans that enable a patient to return to the community. At discharge from inpatient facilities, patients are usually referred for follow-up to community-based agencies. Nurses working in these settings are especially skillful in communication skills (see Chapter 17) and patient safety (see Chapter 36).

Rehabilitation Centres. A rehabilitation centre, a residential institution that provides therapy and restorative training, seeks to decrease clients’ dependence on care. Many centres offer programs to teach the patient, patient’s family, or both to achieve maximum function after a stroke, head or spinal cord injury, or other impairment. Substance rehabilitation centres help clients withdraw from alcohol and drug dependence and return to the community. Nurses in rehabilitation centres collaborate closely with physical and occupational therapists, psychologists, and social workers, working with clients experiencing stress and adaptation (see Chapter 29) and those at risk of challenges to mobility (see Chapter 45) and to safety (see Chapter 36).

Community Sector

Community services are directed at primary and secondary care, described later in this chapter, and should be accessible to clients in locations where they live, work, play, and engage. The focus is on empowerment and community development opportunities that effect change at the broadest social level (Health Canada, 2006). Community health nurses oversee and participate in outreach programs that provide services and locate clients who might not seek care at traditional health care centres. According to the Community Health Nurses of Canada (2011), community nurses work in diverse rural and urban settings such as public health units, home health, family practices, occupational health, outpost stations, the street, faith organizations, schools, and correctional institutions. Nurses practising in the community sector are involved in community-based nursing (see Chapter 4) and caring throughout the lifespan (see Unit V).

Public Health. Public health is committed to ensuring conditions and circumstances in which people can be healthy through appropriate screening, assessment, development, monitoring, and support (i.e., public policy). Whether it concerns environmental, biological, or disease issues, public health differs from many clinical practice settings in its focus on entire populations rather than on individual clients.

Activities related to pandemic planning, severe acute respiratory syndrome (SARS), West Nile virus, H1N1, and global surveillance have put public health in the forefront (see the *Canadian Pandemic Influenza Plan for the Health Sector* [Public Health Agency of Canada, 2009]) with regard to protection and promotion efforts. Public health nurses work closely with a range of health care providers, including medical health officers, therapists, psychologists, nutritionists, and environmental and public health inspectors. Nurses are the primary professionals in public health clinics offering well-baby clinics, school health programs, sexually transmitted infections surveillance, and screening programs, as well as health promotion (e.g., tobacco reduction) and disease prevention programs.

Physician Offices. Physician offices offer PC focusing on diagnosis and treatment of specific illnesses rather than on health promotion. The majority of physicians function as private contractors within the publicly funded health care system, working on a fee-for-service basis. In this setting, nurses record vital signs, prepare clients for examination, and collaborate with physicians to conduct physical examinations, document histories, offer health education, and recommend therapies.

Community Health Centres (CHCs) and Clinics. CHC teams plan, manage, and deliver comprehensive services to designated geographic areas or specific at-risk populations. According to the Canadian Alliance of Community Health Centre Associations (2011), CHCs are the first point of contact offering a range of primary health, social, rehabilitation, and other noninstitutional services and emphasizing prevention, promotion, health education, community development, and partnerships to develop a healthy local community.

Increasingly, NPs and nurses are managing CHCs, with the intention of enabling clients to assume more responsibility for their health. NPs have become CHC team members focused on prevention and supportive services rather than on family practitioner-driven curative and rehabilitative care.

Assisted Living. Assisted-living facilities are community-based residential facilities where adults live and receive a range of support services, including personalized assistance in achieving optimal independence. Personal assistance services “promote maximum dignity and independence through meal preparation, personal hygiene practice, mobility, and socialization.” These facilities usually combine professional and nonprofessional staff on an around-the-clock basis.

Home Care. Canadian health care is shifting from an institution-based system to one in which community care is playing a greater role (see Chapter 4). Home care is the provision of health care services and equipment to clients and families in their homes. Home care is not included in the *Canada Health Act* as a medically necessary service, so the range of public funding varies significantly across jurisdictions (Health Canada, 2010d). All provinces and territories fund assessment and case management, nursing care, and support services for eligible clients. Clients may pay for extra professional or support services through insurance programs or pay-for-service arrangements. The federal government delivers home care services to First Nations people on reserves and Inuit people in designated communities, members of the armed forces and the RCMP, federal inmates, and eligible veterans.

Home care involves primarily nursing care as well as other professional and nonprofessional services, such as physiotherapy; social work; and occupational, respiratory, and speech therapy. Support services are nonmedical services and include personal care, assistance with activities of daily living, and assistance with home management.

Home care was created to provide individualized care for people after hospital discharge but has increasingly included clients in a range of ages from very young to very old; those with mental, physical, or developmental challenges; and those needing recovery to end-stage care. CHA (2009) found home care to be a cost-effective alternative to acute care, maintaining clients at optimal levels of functioning, delaying institutionalization, and providing a viable substitution for health services (e.g., early discharge, home intravenous). Nurses working in home care have experience with all levels of care within the home setting (see “Levels of Care”), as well as complex caseloads. Home care nurses respond to issues of cultural diversity

(see Chapter 9), family nursing (see Chapter 19), and patient safety (see Chapter 36).

Adult Day Support Programs (ADSPs). Adult day support programs are associated with a hospital or long-term care facility or exist independently. As an alternative to hospitalization, continuous health care services are provided for specific clients (e.g., those with dementia, those needing physical rehabilitation or counselling, or those with chemical dependency). According to the Family Caregivers' Network Society (2010), over 2.8 million Canadians provide care and support for an adult family member or friend. ADSPs play a critical role in enabling a caregiver's participation in care while continuing to work. Nurses in ADSPs provide continuity between the care delivered at home and care delivered in the centre. For instance, nurses administer treatments, encourage clients to adhere to prescribed medication regimens (see Chapter 33), link clients with community resources (see Chapter 4), and provide counselling services (see Chapter 19).

Community and Voluntary Agencies. National, provincial, and regional voluntary agencies (e.g., Heart and Stroke Foundation of Canada, Canadian Diabetes Association) meet specific needs. Most voluntary agencies offer programs to educate about, prevent, and detect specific conditions, rather than treat them. Voluntary agencies depend on the help of professional volunteers (e.g., VON [Victorian Order of Nurses]) and lay volunteers (e.g., Meals on Wheels). They offer financial support for training physicians and nurses through fundraising and donations.

Occupational Health. More than 2000 members of the Canadian Occupational Health Nurses Association (2011) deliver integrated occupational health and safety services to individual and communities of workers. RNs certified in occupational health have met specific eligibility requirements, passed a written examination, and achieved a national standard of competency. Occupational health nurses often work with physiotherapists, occupational therapists, and psychologists for large corporations in broad-based programs encompassing the range of promotion, maintenance, and restoration of health and prevention of illness and injury.

Hospice and Palliative Care. A hospice is a family-centred care system that enables a person to live in comfort, with independence and dignity, while living with a life-ending illness. Hospice care is palliative, not curative (see Chapter 28). Its multidisciplinary approach involving physicians, nurses, social workers, pharmacists, and pastoral care staff is crucial. Hospice nurses work in hospitals, free-standing hospices, or the home, caring for patient and family during the terminal phase of illness, at the time of death, and beyond in the form of bereavement counselling to the family and support network.

Parish Nursing. Parish nursing is becoming more popular as faith-based communities promote and maintain members' health. According to the Canadian Association for Parish Nursing Ministry [CAPNM] (2011), a parish nurse is a RN with specialized knowledge who is called to the ministry and affirmed by a faith-based community to promote health, healing, and wholeness. Currently, CAPNM's approximately 160 members promote the integration of faith and health through advocacy, counselling, education, referrals, and linkages to health and intersectoral services (CAPNM, 2011).

Levels of Care

Five levels of health care exist: promotive, preventive, curative (diagnosis and treatment), rehabilitative, and supportive

(including home care, long-term care, and palliative care) (CNA, 2003; WHO, 1978).

Level 1: Health Promotion

The first level of health care, **health promotion**, focuses on "enabling people to increase control over, and to improve their health" (HCC, 2005). Examples include provision of wellness services, antismoking education, promotion of self-esteem in children and adolescents, and advocacy for healthy public policy.

Health promotion takes place in many settings. For example, community clinics offer prenatal nutrition classes that promote health of the woman, fetus, and infant. The *Ottawa Charter for Health Promotion* (the *Charter*) (Lalonde, 1986) lists five action strategies for health promotion: building healthy public policy, creating supportive environments, strengthening community action, developing personal skills, and reorienting health care services. The *Charter* details how health care providers enable clients to make decisions that affect their health. Furthermore, the foundation of health promotion consists of "the fundamental conditions and resources for health [which] are peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice, and equity" (Lalonde, 1986) (see Chapter 1).

Level 2: Disease and Injury Prevention

The second level includes illness prevention services to help clients, families, and communities reduce risk factors for disease and injury (see Chapter 4). Prevention strategies include clinical actions (screening, immunizing), behavioural aspects (lifestyle change, support groups), and environmental actions (societal pressure for a healthy environment) (see Chapter 1).

Level 3: Diagnosis and Treatment

Diagnosis and treatment focus on recognizing and managing clients' existing health problems. Three sublevels of diagnosis and treatment care exist: primary, secondary, and tertiary. These refer to health care activities aimed at individuals, rather than at families or communities.

- **Primary care (PC)** is the first contact of a patient with the health care system that leads to a decision regarding a course of action to resolve any actual or potential health problem. PC providers include physicians and NPS in practice settings such as physicians' offices, nurse-managed clinics, and schools. The focus is on early detection, routine care, and education to prevent recurrences. (Recall and note differences from PHC.)
- **Secondary care** usually occurs in hospital or home settings and involves specialized medical service by a physician specialist or a hospital on referral from a PC practitioner. Secondary care considers definitive diagnosis or clients requiring further diagnostic review.
- **Tertiary care** is specialized technical care in diagnosing and treating complicated or unusual health problems. Tertiary care occurs in regional, teaching, university, or specialized hospitals that house sophisticated diagnostic equipment and perform complex procedures.

Level 4: Rehabilitation

Rehabilitation is the restoration of a person facing life-altering health situations through education, advocacy, collaboration, and research (Canadian Association of Rehabilitation Nurses, 2010). Rehabilitation occurs after a physical or mental health illness, injury, or chemical addiction or is related to chronic

illness, disability, frailty, and aging. As a condition stabilizes, rehabilitation assists clients to return to their previous level of function or reach an optimal level of function, thereby enhancing quality of life while promoting independence and self-care.

Rehabilitation nurses often work with physical, respiratory, occupational, and speech therapists. Ideally, rehabilitation begins the moment a patient enters a health care setting for treatment. For example, some orthopedic programs have clients undergo physiotherapy exercises before major joint repair so as to enhance their recovery (see Chapter 35). Nurses have a key role in the continuity-of-care aspects of rehabilitation across agencies and settings.

Level 5: Supportive Care

Clients of all ages with illnesses or disabilities that are chronic (i.e., are long term) or progressive (i.e., worsen over time) may require supportive care. **Supportive care** consists of health, personal, and social services provided over a prolonged period to people who are disabled, who do not function independently, or who have a terminal disease. With increasing life spans, escalating chronic conditions, and diverse care settings (i.e., institutional, community, and home), demand for supportive care will continue to grow. Two examples of supportive care include the following:

Palliative care serves people living with progressive, life-threatening illnesses, or conditions. Palliative care, whether provided in hospital, hospice, or home, addresses physical, emotional, social, and spiritual needs of the patient and family.

Respite care provides short-term relief or time off for family caregivers by health care providers and/or trained volunteers in either institutional (i.e., ADSP) or home settings.

Challenges to the Health Care System

Canada's health care system is faced with many issues and challenges, categorized either as cost accelerators or as costs associated with providing equal care and access for all.

Cost Accelerators

Technologies. New technologies, such as new-generation antibiotics, diagnostic imaging equipment, and specialized beds, have become integral in the treatment of diseases and disabilities. The effectiveness of technical advances has reduced mortality and morbidity rates; however, costs have increased with these innovations.

As an essential element of future health care delivery, **e-health** (see Chapter 16) encompasses and is embedded in a number of health applications from administrative to direct care. There is an emphasis on developing a national health info-structure to support direct care, telehealth, **m-health** (mobile applications), **remote monitoring**, and maintenance of **electronic health records (EHRs)**. (See Chapter 15 for more on EHRs.) Remote monitoring supports information-based, near real time health care by using wireless electronic capacities to link medical providers to patients using instruments (e.g., blood pressure monitors) who are not located with the providers. EHRs are essential for interprofessional collaborative practice and sharing of records across the health care continuum. **Nursing informatics** is an emerging area that "integrates nursing, its information and knowledge and their management with information and communications technologies to improve the health of people, families, and communities

worldwide" (Canadian Nursing Informatics Association, 2011).

Demographics. As the population ages, chronic and age-related diseases are increasing in frequency, largely because older people are more likely to become ill and disabled. They require more treatment and drugs, resulting in higher costs to the health care system. According to Statistics Canada (2011), nationally, 14.1% of Canada's population was made up of older adults aged 65 and over, up from 13.4% in 2007. This trend will persist over the next 20 years, as each year more than half a million baby boomers will be turning 65 (Corbella, 2008). Another demographic contributing to higher health care costs since the mid-1980s is increasing maternal age.

Consumer Involvement. Canadians are better informed than ever about their health care options and demand a high level of **quality care**. For example, clients might request an expensive diagnostic test such as magnetic resonance imaging (MRI), whereas previously an X-ray would have sufficed.

There is a growing presence of and demand for **self-care** activities to enhance health, prevent disease, evaluate symptoms, and restore health either independently or in collaboration with health care providers (Consumer Health Products-Canada, 2009).

Equality and Quality

The Canadian health care system strives to provide quality care and access to care for all.

Income Status. Income assistance programs for older adults and social assistance recipients cover some health care expenses not covered by Medicare, such as optometry, dentistry, and pharmaceuticals. Canadians with low wages experience poorer access and poorer health status. For example, they tend to seek dental and optometric care less than other Canadians.

Cultural Competence. Canada is a country of diversity, creating an imperative for a health care system and providers to be responsive and respectful (see Chapter 9).

As discussed earlier, the federal government has a key role in the provision of health care services to First Nations and Inuit people. Since 1986, a movement to transfer responsibility and control for health services to First Nations and Inuit governance has emerged (Health Canada, 2003). The shift in the health structures and PHC seem to hold the promise of aligning with Aboriginal peoples' beliefs, especially with regard to holism and integration.

Immigration has shaped Canada's population historically. Between 2001 and 2006, newcomers represented two-thirds of the population growth, with significant influxes in urban centres and neighbouring municipalities (Chui et al., 2007). Linguistic and cultural diversity is immense, with more than 70% of newcomers reporting a mother tongue other than English or French (mostly Chinese) (Chui et al.). Variations in the health status of the newcomers are based on their reasons for immigration, place or circumstances of origin, and social supports (Wayland, 2006). Issues of income, psychological well-being, and ethnic support are important aspects of adjustment and risk reduction (Wayland).

Evidence-Informed Practice (EIP). Nursing practice is constantly evolving, and nurses must remain responsive to new developments, innovations, and information. According to Cleary-Holdforth (2009), **evidence-informed practice** (see Chapter 6) is a critical aspect of clinical decision making and an influential strategy for nurses to improve patient outcomes.

EIP resources are available on CNA's portal called NurseONE/INF-Fusion (<http://www.nurseone.ca/>). NurseONE is a personalized, interactive Web-based resource providing a gateway for nurses and nursing students to search for information about enhancing patient care, managing their careers, pursuing lifelong learning opportunities, and connecting to colleagues (Bassendowski et al., 2008).

Quality and Patient Safety. According to the International Society for Quality in Health Care (ISQua) (2007), quality practice and performance improvement underpin the work of the health care team across the continuum of care. Quality and safety in health care involve health facilities and providers, clinicians, and other professionals, providing the right care for the right people at the right time and in the right amount (ISQua, 2007). ISQua reported that consumers consistently rank quality and safety of care high among their concerns.

According to Baker and Norton (2004), approximately 70,000 preventable adverse events occur annually in Canadian hospitals, which translated to between 9000 and 24,000 deaths in 2000. One out of every nine clients contracts an infection while in hospital, a statistic mirrored in the number of medication-related errors (Baker et al., 2004). The Canadian Patient Safety Institute (2010) provides leadership on patient safety and fosters a culture to improve care through innovation and professional development.

Quality Workplaces. Health care is delivered in a diverse range of environments, a situation that challenges quality issues and affects recruitment and retention. Sustainable and quality workforces, organizational efficiencies, and improved patient care are related to improved work environments (Health Canada, 2010c). The Pan-Canadian Health Human Resource Strategy (PC HHRS) articulates approaches to enhancing work and learning conditions necessary to maintain an experienced, dedicated and skilled workforce for high quality, safe, and timely care (Health Canada, 2010c).

Privatization of Services. Governments are struggling to maintain the principle of universality against the benefits and challenges of privatization. At present, not all health care services are available and accessible to all Canadians. For example, infertility treatments and laser eye surgical procedures are performed in private offices, available to clients who can afford them. Discussions persist about what constitutes "medically necessary services" and what makes up universal "core services," with many experts contending that the survival of medicare depends on privatizing more parts of the health care system.

Health Care Human Resources. In 2006, more than 1 million people (about 6% of the total workforce) in Canada worked directly in health-related occupations (Chui et al., 2007). Despite these numbers, accessibility to health care services is compromised by shortages of physicians, nurses, and other health care professionals. Health Canada (2010c) states health and human resources planning must occur within the broader health care system, recognizing systemic challenges of wait times, patient safety, and bed closures.

Aboriginal peoples are significantly under-represented in health professions. Health Canada established a five-year initiative, known as the Aboriginal Health Human Resources Initiative (AHHRI), focusing on increasing Aboriginal representation in health professions and retention of health care providers successfully working with Aboriginal peoples as part of the PC HHRS. The AHHRI-Phase II was extended in December 2010.

Nursing's Future in the Emerging Health Care System

This chapter provided extensive discussion about restructuring and challenges within the Canadian health care system. Within the context of restructuring and complexities within the Canadian system, nursing roles continue to evolve and diversify. In the future, nurses will increasingly be regarded as critical stakeholders, partners, and providers within the emerging health care system. Nurses will continue to draw on their historical legacy, forge ahead, and use evidence to inform their pursuit of excellence and quality in care, while advocating and innovating for the benefit of their clients.

❖ KEY CONCEPTS

- Medicare is a key component of Canada's social safety net.
- Government plays a major role in the Canadian health care system by co-funding national health insurance and by setting health care policy in accordance with the *Canada Health Act*.
- The *Canada Health Act* forbids extra billing and user fees while articulating the principles of public administration, comprehensiveness, universality, portability, and accessibility.
- Health care services are provided in institutional, community, and home settings; across all age groups; and for individual, family, group, community, and population clients.
- Five levels of health care are promotive, preventive, curative, rehabilitative, and supportive.
- Escalating costs and consumer expectations challenge the health care system to seek and deliver innovative, efficient, and quality care.
- Issues of equality, access, interprofessional approaches, and continuity of care challenge the health care system.
- The rise of PHC and home care is a result of health care reforms.
- Successful health promotion and disease prevention programs help clients acquire healthier lifestyles and achieve a decent standard of living.
- Demographic, geographical, and technological realities affect the functioning and restructuring of the Canadian health care system.
- The existence of sufficient, diverse, and qualified human health resources is a key challenge to the Canadian health care system.
- Enhancing the health of Aboriginal peoples in Canada is a significant challenge to society and to the health care system.
- Nurses must continually seek out information and evidence to remain responsive to providing quality, culturally competent, and safe care.

❖ CRITICAL THINKING EXERCISES

1. Debate the following issues respecting the future of the Canadian health care system: escalating costs, privatization, continuity of care, electronic health records.
2. Consider and describe how the national economy and technology have changed the Canadian health care system. What are the implications for nursing?
3. Mr. W., a 68-year-old widower with no immediate family supports, is scheduled to have major surgery to replace the joint in his hip. He is generally in good health and lives in a seniors-only apartment complex in the centre of town. After surgery, he will need extensive therapy in order to walk. Describe the types of health care services, patient safety issues, and technological supports that might play a part in his care.

❖ REVIEW QUESTIONS

- Canada has undertaken an effort to reduce wait times, reduce duplication of tests, and support coordination of care through which agency?
 - Canada e-Health
 - Canada Infoway
 - Canada m-Health
 - Electronic Health Records
- Which of the following people are insured under the *Canada Health Act*?
 - Aboriginal peoples
 - RCMP members
 - Members of military services
 - Persons in transit between provinces
- Public health focuses on
 - Treatment
 - Promotion
 - Intervention
 - Institutionalization
- The *Canada Health Act* embraces the following five principles:
 - Public administration, comprehensiveness, universality, portability, accessibility
 - Social justice, equity, acceptability, efficiency, effectiveness
 - Accountability, equality, economy, collaboration, coordination
 - Insured health services, provider compensation, hospital services, community care, and pharmaceuticals
- An adult day support program is an example of a(n)
 - Home care agency
 - Institutional agency
 - Community agency
 - Ambulatory care centre
- What are the five levels of health care services?
 - Promotive, preventive, curative, rehabilitative, supportive
 - Prevention, protection, diagnosis, treatment, palliative care
 - Promotion, prevention, treatment, PHC, diagnosis
 - Assessment, diagnosis, planning, implementation, evaluation
- Which trend is most critical in the future health human resources plan?
 - Keeping sufficient physicians
 - Ensuring adequate providers in rural and remote areas
 - Ensuring ethical recruitment and retention
 - Increasing number of health providers to respond to emerging health needs
- Which is not a cause of Canada's increasing health care costs?
 - Workplace injuries
 - Aging population
 - New technologies and pharmaceuticals
 - Chronic and emerging diseases

- A nurse organizes a blood pressure screening program as a _____ strategy.
 - Health promotion
 - Disease prevention
 - Continuing care
 - Rehabilitation
- Provision of specialized medical services by a physician specialist or a hospital is
 - Primary care
 - Primary health care
 - Secondary care
 - Tertiary care

❖ RECOMMENDED WEB SITES

Canadian Health Services Research Foundation: Research Theme: Primary Health Care: http://www.chsrf.ca/research_themes/ph_e.php

This site addresses initiatives of the foundation that relate to PHC reform and research.

Canada Health Infoway: <https://www.infoway-inforoute.ca/>

A not-for-profit corporation created by Canada's First Ministers to foster and accelerate development and adoption of EHR systems with compatible standards and communication technologies.

Canadian Institute of Health Information: <http://www.cihi.ca>

A not-for-profit organization seeking to improve the health care system and the health of Canadians by providing health information.

Canadian Public Health Association: <http://www.cpha.ca>

A national, not-for-profit association seeking excellence in public health nationally and internationally.

Health Canada: <http://www.hc-sc.gc.ca>

This site provides links to information about the Canadian health care system, such as the *Canada Health Act* legislation, and federal reports.

Canadian Patient Safety Institute: <http://www.patient-safetyinstitute.ca>

This institute was established to build and advance a safer health care system for Canadians. It reports on activities in leadership across health sectors and health care systems, highlights promising practices, and raises awareness with stakeholders and the public about patient safety.

Health Quality Council (Saskatchewan): <http://www.hqc.sk.ca>

The Saskatchewan Health Quality Council was established in 2002 through provincial legislation to improve health care in Saskatchewan by encouraging the use of best evidence.

Health Council of Canada: <http://www.healthcouncilcanada.ca/>

The Health Council of Canada fosters accountability and transparency by assessing, monitoring, and reporting progress in improving quality, effectiveness, and sustainability of the health care system for the well-being of Canadians.

The Development of Nursing in Canada

Written by Janet C. Ross-Kerr, RN, BScN, MS, PhD, and Sonya Grypma, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss the historical development of professional nursing.
- Discuss the historical development of nursing education in Canada.
- Discuss the historical development of nursing practice in Canada.

Over the centuries, the goals of nursing have been to help people maintain their health and to provide comfort and care to the sick. Modern nursing is a professional discipline with a unique body of knowledge applied to the needs of individuals and families. The foundations of professional practice emerge from historical and philosophical traditions in nursing and health care, social policy and practice, and ongoing research in nursing. It is interesting to explore the origins of nursing because they have contributed to modern nursing. The evolution of nursing has brought the profession to a challenging and exciting time in its history. There are tremendous opportunities to improve the health and quality of life of patients and communities with advances in professional knowledge and practice.

The philosophical and theoretical basis of the profession provides the necessary foundation for practice (see Chapter 5). Henderson's (1966) famous definition of nursing was adopted by the International Council of Nurses (ICN) in 1973 and continues to be the primary description of the role of the nurse:

The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health [and] its recovery, or to a peaceful death that the client would perform unaided if he had the necessary strength, will, or knowledge. And to do this in such a way as to help the client gain independence as rapidly as possible. (p. 15)

As a profession, nursing is committed to public service. The practice of nursing requires specialized knowledge that must be acquired and carries a high degree of responsibility. Nursing has practical and theoretical components, is motivated by altruism, and is based on ethical standards. The profession evolves as society, health care, and

social policies change. This chapter traces the roots of the nursing profession over many centuries to its establishment and development in Canada. Although there has been a dramatic increase in the nature and extent of knowledge and skills required for nursing, the professional mandate has remained relatively constant over time and continues to be an inspiring force for the profession. The transformation of the profession to the modern era is highlighted.

Highlights of World Nursing History

Nursing's historical roots are deep and honourable and can be traced over many centuries. In the sixteenth century B.C., the ancient Egyptians recognized the importance of preventing illness and maintaining health. They understood that a good diet was important in maintaining health and consumed a reasonably well-balanced diet of fruits, vegetables, fish, milk, legumes, seeds, and oil. Priest-physicians ministered to the people, using herbs to relieve pain and a variety of treatments for illness that were based on spiritual or mythological beliefs about its causation. The Papyrus Ebers and the Edwin Smith Papyrus came to light in Thebes (now Luxor) in 1862 and document how the Egyptians dealt with health and illness as far back as 3300–1500 B.C.

The theories of health and illness of the ancient Egyptians provided a framework for the development of medicine in ancient Greece. Although the early Greeks believed in the spiritual causes of disease, Hippocrates (circa 460–370 B.C.) was the first to make observations of patients and develop treatments on the basis of symptoms. He founded a school of medicine and wrote numerous books on disease. Hippocrates is considered the father of scientific medicine and Western medical ethics; he developed methods of treating disease and establishing ethical principles upon which practice was based. Through his influence, medicine developed into a science. Galen (circa A.D. 130–203), another Greek physician-scientist, made important contributions to the field of physiology before becoming physician to the gladiators. Knowledge acquired through Galen and other Greek physicians had a significant influence on the Romans.

The Romans recognized the importance of fresh water and hygiene for public health. As their cities grew and the water supply became inadequate, Roman engineers developed aqueducts in Rome between 312 B.C. and A.D. 226 to carry fresh water from distant springs. They also developed public baths and constructed public toilets and sewers, which greatly improved the health of the population.

The ancient Hebrews believed in a spiritual basis of illness and that following the Ten Commandments promoted health. They also recognized the importance of nutrition and developed dietary laws that protected the public by prescribing what foods could or could not be eaten together, or eaten at all, as well as guidelines for safely eating the meat of slaughtered animals. Nurses cared for the sick in the home and community and served as midwives during childbirth.

During the early Christian period, with the emphasis of Christianity on love for others, nursing became a caring service undertaken mostly by women. The Benedictine Order originated with St. Benedict of Nursia in A.D. 529 and is the oldest of the Catholic nursing orders. Fabiola, a well-to-do Christian woman in Rome, offered respite to ill and fatigued pilgrims travelling to the Holy Land. Later, during the twelfth and thirteenth centuries, hospitals were built to provide care for

the sick. The Knights Hospitallers of the Order of St. John of Jerusalem emerged from the Benedictine nursing tradition to become one of a number of religious orders formed during the Crusades (eleventh to thirteenth centuries) that were committed to caring for and defending pilgrims. When the Protestant Reformation took hold in Europe after the Crusades, monasteries were disbanded, and the hospitals and other institutions where monks and nuns cared for the sick and weary were closed. When new hospitals were built, untrained and unsuitable individuals were responsible for nursing patients. Conditions deteriorated as lack of sanitation prevailed and disease spread rapidly.

During the seventeenth century, conditions began to improve and there was greater emphasis on nursing. St. Vincent de Paul founded the Sisters of Charity in 1633 to care for the sick, poor, and orphaned. Because this order was non-cloistered (the first such order), the nuns were able to go into the community to care for people. For the most part, women who entered convents to become nurses came from the upper classes and were well educated. In Germany, Pastor Theodore Fliedner established his now rather famous Institute of Deaconesses at Kaiserwerth in 1836 to prepare women to serve as nurses.

Early History of Nursing in Canada

The roots of nursing and health care in North America may be found in the values and ideals of the European settlers in New France. At a time when knowledge of disease was primitive, technology was virtually nonexistent, and a few herbal remedies were the only medicines available, the practice of nursing developed as an integral part of the emerging health care system. Nursing care was often the sole weapon in fighting infectious disease. Its importance is underscored in accounts of the devastating epidemics of smallpox, diphtheria, cholera, typhus, trachoma, scarlet fever, and other infectious diseases that ravaged the population in continuing episodes (Paul & Ross-Kerr, 2011).

A long-established indigenous society existed in North America before the arrival of the first settlers. At the time of the first sustained contact with European people, the estimated number of indigenous people in North America was about 500,000, although this is acknowledged as probably a conservative number (Royal Commission on Aboriginal Peoples, 1996). The Aboriginal peoples also had health care knowledge of their own, including the use of herbal remedies to relieve symptoms of some diseases. Even after municipalities began to build hospitals and the number of doctors and nurses in western Canada grew after 1890, acquiring such services remained prohibitive due to cost and distance. Thus, during the late nineteenth and early twentieth centuries, indigenous women played essential roles within their own and newcomer communities as midwives, nurses, and caregivers. They used indigenous knowledge to care for many white settlers in western Canada (Burnett, 2008).

The First Nurses and Hospitals in New France

In 1608, Samuel de Champlain selected Quebec as the site for a colony of settlers to support the growing fur trade. For the next two decades, the first colonists in New France provided their own health care. The first laywoman to provide nursing care in New France was Marie Rollet Hébert. She and her husband, Louis Hébert, who was a surgeon-apothecary,

emigrated at the request of Champlain in 1617. Mme Hébert became the first woman to emigrate to the new world from France and cared for Native people and settlers alike. Her husband's apothecary and agricultural skills helped prevent starvation and mitigate illness (Brown, 2002). Although she was a layperson, Mme Hébert extended care to Aboriginal people and settlers who were ill, just as she would for ill family members.

The first nurses to tend the sick in a type of health care centre were male attendants at a "sick bay" established at the French garrison in Port Royal in Acadia in 1629 (Gibbon & Mathewson, 1947). The Jesuit priests, who were missionary immigrants to New France, also served as nurses. Their care for the sick aided their mission to convert the Aboriginal people to Christianity. Their call for assistance led to the missionary efforts of religious orders and laypersons, all of whom came to New France voluntarily to assist the Jesuits.

Because the Protestant Reformation was unsuccessful in France, religious orders there remained strong and sent nuns to the missions in New France. Most of the women who came to New France were motivated by Christian ideals of educating Native children and caring for the sick. Although small in number, these women led the young colony's efforts in health care and teaching. They proved remarkably resilient as they battled smallpox epidemics and tended to people injured in the Iroquois wars.

The first nursing mission was established in 1639 at Sillery, outside the citadel of Quebec, by three Augustinian nuns who were Hospitalières de la Miséricorde de Jésus. No sooner had they arrived than they found themselves overwhelmed with patients from the raging smallpox epidemic. As the population grew, they had enough new recruits that they no longer needed to ask for nuns to come from France to assist them. It has been said that "Quebec . . . had a seminary, a hospital, and a convent, before it had a population" (Parkman, 1897, p. 259). This mission later became known as Hôtel-Dieu, Quebec's first hospital. As a result of the Iroquois wars, the nuns abandoned this mission at Sillery in 1644 and moved it inside the citadel. An indication of the quality of the care provided by the nuns is the fact that 93% of the patients admitted to the Hôtel-Dieu of Québec survived (Rousseau, 1977; Hamelin, 1981).

In 1641, Jeanne Mance came to New France to found a hospital in the yet unsettled region of Ville-Marie (later Montreal); Mance and her fellow travellers were not warmly received. Their intentions to care for the sick were viewed with suspicion by the settlers at Quebec, where they spent the winter. When she arrived at Ville-Marie in 1642, Mance was the only person with health care knowledge in the new settlement. She was a leader in the community and became an inspiration for later generations of nurses (Box 3-1). It is important to recognize that it was nurses rather than physicians who both provided and administered health care for the Native peoples and settlers in New France from the outset of the settlement.

The Birth of Home Visiting and the Grey Nuns

A uniquely Canadian order of nuns, the Sisters of Charity of Montreal, was formed in 1738 by Marguerite d'Youville, a widow who was a niece of the explorer La Vérendrye. The Grey Nuns are considered the first visiting nurses in Canada. They were also the first noncloistered order, beginning as a small group of women with charitable intentions who "agreed

to combine their possessions in a house of refuge chiefly for the poor" (Gibbon & Mathewson, 1947, p. 45). According to Eccles, "Poverty was not regarded as a sin or a crime, but as a fault in the fabric of the society that had to be mended" (1974, p. 69). They engaged in many activities in order to subsist, such as admitting wealthy paying guests to hospital as well as patients who required care. Because what they were doing was highly unusual, some were hesitant to trust them and they were called "les soeurs grises," a derogatory term with a double meaning, that is, the Grey Nuns and the "tipsy nuns." However, the goodness of their intentions was clear and they were respected for their work. They proudly referred to themselves as the Grey Nuns from then on and were given a charter to take over the General Hospital of Montreal. To meet their expenses, they had to be very innovative; they made military garments and tents, started a brewery and a tobacco plant, and operated a freight and cartage business (Ross-Kerr, 2011).

Nursing During the British Regime

During the war between the British and the French in 1756, the Grey Nuns designated a ward of the General Hospital of Montreal for the care of English soldiers, thus caring for soldiers on both sides of the conflict. The status of nursing and the quality of care provided differed markedly between Canada and Great Britain. Nursing in Britain had fallen into disrepute after Henry VIII's renunciation of the Catholic Church. The nursing orders of nuns, which had previously provided the nursing services in the large London hospitals, were replaced by women of questionable morals and little knowledge. However, nursing remained strong in early Canada because of the influence of France, where nursing was performed at a higher standard. In the transfer of authority for Montreal to the British in 1760, General Amherst declared: "Of the goodwill I have to a Society so worthy of respect as that of the Monastery of St. Joseph de l'Hôtel Dieu de Montréal, which can count so far as the British Nation is concerned on the same protection that it has enjoyed under French rule" (Gibbon & Mathewson, 1947, p. 1).

Infectious diseases carried by immigrants and travellers spread rapidly in the British colonies. The increasing populace and continuing epidemics created a need for more health care facilities. In areas not served by the French-Canadian nursing orders, institutions were established with standards similar to those in Britain (Canadian Nurses Association [CNA], 1968). Laywomen offered services and organized groups to provide proper care, but because they lacked knowledge and skill, these efforts were largely unsuccessful. The established French-Canadian orders expanded their services, and new English-speaking orders were founded to help the sick and poor.

Health Care in the West and the Grey Nuns

In 1844, four Grey Nuns embarked on a perilous canoe journey from Montreal to St. Boniface, Manitoba, where their mission was to care for the sick. Soon after their arrival, a series of epidemics began. The nuns visited the sick at home, where they cared for people with measles, dysentery, and smallpox, and treated them with medicines and local herbs.

In 1859, another group of Grey Nuns travelled from Montreal by rail through the United States and then north to St. Boniface. After resting for a time, they set off by ox cart over rough terrain to arrive in what is now Alberta to establish their first mission in Lac Ste. Anne, where they visited patients in their homes and cared for them in the convent. Arriving before

► BOX 3-1 Milestones in Canadian Nursing History

Jeanne Mance, 1606–1673

Jeanne Mance was born in a wealthy family in Langres, France, in 1606. She was the daughter of a wealthy legal advisor to the court of the King of France and decided early to devote her life to God. She learned about New France from a cousin, a Récollet priest who had served there. She gained nursing knowledge and skills in Langres, where an epidemic of plague occurred and many people were wounded in the Thirty Years' War. Supported by a wealthy widow who wanted to finance a hospital at Ville Marie, Jeanne Mance sailed to

New France with Paul de Chomédey, Sieur de Maisonneuve, and his band of 40. Maisonneuve's mission was to establish a settlement at Ville Marie, but arriving in Quebec after a two-month voyage, the settlers learned that the governor was suspicious of their mission, and he tried to dissuade them from it.

They decided that it was too late in the summer to try to build the colony, so they remained in Quebec, involving themselves in the community. Mance spent time learning about nursing and health care in New France from the Augustinian nuns in their hospital.

In the spring, the settlers set out for Ville Marie in three boats and immediately began building houses and the Hôtel-Dieu. The next year, during an attack by the Iroquois, several settlers were killed, and others were taken hostage. The remaining settlers managed to finish the hospital and build a stockade around their colony. However, the attacks

increased, and Mance was kept busy caring for both wounded settlers and Aboriginal people. By 1649, the settlers' funds were low, and the colony was close to having to disband. Mance sailed to Paris, where she raised money and recruited settlers. Over the next few years, relations with the Iroquois continued to be poor. A guard was placed at the hospital and Mance slept within the fort. In 1650, the Iroquois killed 30 of 70 settlers.

Maisonneuve went to France in 1651 to gain further support and did not return for two years. This period was difficult, but Mance held the colony together during his absence. After a truce was reached between the French and the Iroquois in 1654, Mance was able to move back to the Hôtel-Dieu. In 1657, Mance fell on the ice, fractured her right arm in two places, and dislocated her wrist; as a result, she experienced continuing disability. She decided to make another trip to France to ask the order of nuns at La Flèche to come and help her in the hospital. While in Paris during prayer at the Seminary of Saint Sulpice, she discovered she could move her arm without pain, and it healed miraculously. She made her last trip to France in 1663, again to solicit funding for the colony because it was, again, close to bankruptcy. En route back, she contracted typhus and nearly died. She was shocked to find upon her return that Maisonneuve had been replaced as governor. In declining health, Mance was less able to help at the hospital. She died peacefully in her sleep in 1673.

As well as founding and managing the Hôtel-Dieu, Mance assisted Maisonneuve in running the colony as confidant, advisor, and accountant. She is hailed as a founder of the city of Montreal. Today, the Canadian Nurses Association awards its highest honour in the name of this courageous pioneer.

most of the settlers, the sisters established systems of health care to care for the sick. Demand from the populace was such that they later built a separate hospital building. Later, they established small missions in what is now northern Saskatchewan and the Northwest Territories to provide health care in Aboriginal settlements. In 1895, they were asked to construct a hospital in Edmonton (the General Hospital) because settlement was burgeoning there.

During the Northwest Rebellion of 1885, nurses and physicians were called to duty to care for those wounded in the rebellion of Métis and First Nations people against the governing authority of the Dominion of Canada. Among those who responded to the call for "trained" nurses were six Sisters of St. John the Divine, under the leadership of Mother Hannah Grier Coombs. Established in Toronto only a year earlier as the first Canadian Anglican Sisterhood, the group arrived at the base hospital in Moose Jaw after a six-week journey from Toronto. Two months after Louis Riel's surrender, the Sisters returned to Toronto, where they established the first surgical hospital for women (Domm, 2010).

The Nineteenth Century and Florence Nightingale

The movement to improve standards of nursing care in the mid-nineteenth century was spearheaded by Florence Nightingale, who is considered the founder of modern nursing. Critical public acclaim for her work in the Crimea in which the lives of thousands of wounded British soldiers were saved through good nursing riveted public attention upon the need for change. The comparability between the types of roles fulfilled by nurses trained by Nightingale in the school she

established and the roles customarily expected of women in nineteenth-century Britain was sufficiently evident that nursing achieved respectability and acceptance as a suitable field of work for women outside the home. In making this transition, nursing joined teaching, which had earlier become the first area of work to beckon to laywomen (Jackel, 1985). As with teaching, altruism and service were key elements in achieving public acknowledgement of nursing as particularly appropriate for women's abilities. Remarkable advances in health and health care and the rise of the hospital as a centre for care created a need for an increasingly large nursing workforce, and the nursing profession became one of the most significant avenues of work for women in this century.

Brought up in a wealthy family, Nightingale railed against the customs of her time that did not allow middle- and upper-class women to work outside the home: "Why have women passion, intellect, moral activity—these three—and a place in society where no one of the three can be exercised?" (Nightingale, 1872/1979). She was well educated and, against the wishes of her family, sought to prepare herself for nursing in 1850 by travelling to Kaiserwerth, Germany, where she worked with the German deaconesses under Pastor Fliegener. In 1853, she accepted the post of superintendent at Harley Street Hospital in London. When reports reached London of the appalling conditions for wounded British soldiers, Nightingale was asked to organize a group of nurses to go to the Crimea in 1854.

Nightingale and her staff of nurses made every possible attempt to care for the wounded and make them comfortable in ways that would foster their recovery. These women were

able to achieve dramatic reductions in morbidity and mortality rates, saving the lives of thousands of wounded British soldiers by applying principles of cleanliness and comfort to nursing care. Accounts of Nightingale's work were distributed to the British press by a reporter covering the war. She achieved worldwide fame because of her success in reducing morbidity and mortality through exemplary nursing care. A remarkable shift in public attitudes toward the acceptability of women doing nursing outside the home occurred as a result of her work.

At the same time, remarkable advances in health care and the expansion in the number and importance of hospitals created a need for nurses, and the nursing profession became one of the most significant avenues of work for women in the nineteenth century. Nursing thus became an instrument of women's emancipation against the prevailing middle-class restrictions on women working outside the home.

After remarkable service during the Crimean War, Nightingale became an advocate for the health of people, reform of the health care system of the British army, and educational preparation for nursing. She made her views known through voluminous writings and lobbied members of Parliament and acquaintances to support and act on her views. She drew conclusions from health data that she collected and analyzed, thus becoming known as the first health statistician. Nightingale is the subject of a large, ongoing scholarly writing project spearheaded by McDonald (2010) that incorporates the most significant analyses of her work to date.

Globalization and the Emergence of Modern Nursing

The history of modern nursing, at its heart, is a story of globalization. Nursing history is strewn with examples of nurses travelling across geographic and national boundaries to bring nursing service and training to communities in need (Grypma & Wu, 2012). In 1639, the first Catholic *religieuses hospitalières* sailed from France to New France to work at the Hôtel-Dieu de Québec, the first hospital in America north of Mexico (Violette, 2005). In 1819, France sent the Sisters of St. Joseph of Cluny to West Africa to engage in medical missions in Senegal (Grundmann, 2005). Starting in 1844, the Grey Nuns travelled from Montreal to remote settlements in Canada's west and north where, in some regions, their influence has continued until the present day (Canadian Broadcasting Corporation, 2010; Figure 3-1). Indeed, Catholic religious orders originally based in Europe were instrumental in the development of hospitals and nursing services in the United States, Canada, and Australia (Nelson, 2001; Paul, 2005). At the same time that Florence Nightingale's formal, standardized method of hospital-based nurses training and practice was gaining popularity in the late nineteenth century, a unique set of sociopolitical factors converged to set the stage for a new Anglo-Protestant brand of missionary nursing—and the birth of Canada's overseas missionary nursing movement.

Missionary Nursing

The centrality of Christian mission to three centuries of Canadian nursing peaked with the missionary movement that started in China in the late 1880s and spread across the globe—particularly Asia and Africa. In the late 1880s, China's defeat in the Opium Wars, the women's suffrage movement, the establishment of professional nursing education, advances in

transportation, and the evangelistic student missionary movement converged to provide an unprecedented opportunity for unmarried, ambitious, and intelligent women looking for a way to express their religion in practical terms—as missionary nurses (Grypma, 2012). When the Presbyterian Church in Canada commissioned its first missionary nurse, Harriet Sutherland, to China in 1888, it initiated a wave of an estimated 100 Canadian missionary nurses to China (Figure 3-2). Before Mao Zedong's expulsion of foreigners from China in 1949, these Canadian nurses helped to establish hospitals and training schools in at least five provinces of China. They were among the cadre of Western missionaries credited with the birth and growth of modern nursing in China (Grypma, 2008). Although Canadian missionary nursing would continue in other regions, after the closure of the China field in 1949, missionary nursing moved from the centre to the margins of Canadian nursing practice (Grypma, 2007).

Nursing in Remote Regions of Canada

Remote nursing is a distinguishing feature of Canadian nursing. Outpost and outport nursing stations provided care for northern, newcomer, and Aboriginal communities dispersed across Canada's vast landscape. Since the early

Figure 3-3 Red Cross nurse stopping for lunch, Pouce Coupe, British Columbia, circa 1920s. **Source:** Glenbow Archives, NA-2903-67.

twentieth century, people living in regions considered too small or too remote for hospitals or physician care depended on nurses for their health care needs. Nursing work in remote regions was crucial and all encompassing. In the absence of physicians, nurses in outpost and outport nursing stations provided public health, diagnostic, and emergency medical services. Nurses learned and practised medical skills independently through necessity. Having experienced high levels of independence, northern nurses resented and resisted situations that called for subservience to physicians or other “southern” authorities who were keen to restrict their care (Rutherfordale, 2008).

The Grenfell Mission relied heavily on nurses in its efforts to provide health care for people living along hundreds of miles of coastline in Newfoundland and Labrador between 1894 and 1981. In addition to standard nursing duties, the station nurse’s responsibilities involved operating the dispensary, midwifery, public health, first aid, and dentistry (Coombs-Thorne, 2010). Similarly, nurses working at Red Cross Outpost stations in Ontario between 1922 and 1984 acquired diverse skills considered more in the purview of physicians, including suturing wounds, administering anaesthesia, taking X-rays, and diagnosing illnesses (Elliott, 2010) (Figure 3-3).

Prior to World War II, living conditions for northern populations—primarily Aboriginal—were appalling. Most Western health care to the Arctic was provided under the auspices of Anglican and Roman Catholic churches as “home” missions. In northern Saskatchewan, there was an almost complete absence of government-run services. The end of World War II brought an onset of resource development in northern regions of Canada. The Canadian government increased efforts to provide health care in the Canadian Arctic and, by 1963, the

“Indian and Northern Health Services” branch had a staff of 2500 nurses, doctors, dentists, and administrators (Rutherfordale, 2010). In northern Saskatchewan, nursing was one of many institutions introduced into the region to modernize and improve people’s lives (McBain, 2010). Nursing stations and nurses were vital in providing much-needed professional health care. Those who worked in these settings had opportunity to develop skills, confidence, and independence not typical of—or transferable to—urban hospital settings.

Gender and Diversity in Nursing

For much of its early history, nursing in Canada was considered a suitable profession for young, unmarried, white, Christian women. Since the 1960s and 1970s, the nursing profession has become increasingly aware of the need for gender balance and cultural, ethnic, and religious diversity. As a profession, nursing is in transition from one that has been predominantly female in character to one that is gender balanced. Traditional societal values that negate nurturing roles for men have been changing. However, even though the number of men employed in nursing in Canada has increased, the most recent statistics show the proportion of male nurses as being only 6.0% of the total nurse population, a slight increase over the 4.7% it represented in 2000 (CNA, 2006). This is remarkable at a time when the proportion of women in traditionally male-dominated professions has increased at a phenomenal rate. O’Lynn and Tranbarger (2006) pointed to communication problems, reverse discriminatory practices, and gender-based barriers for male students in nursing. However, although many factors have deterred men from pursuing careers in nursing, some of the negative influences are slowly beginning to change.

Canadian society has also become multicultural. The increase in racial, ethnic, and cultural diversity has meant that individuals of different races, ethnic descent, and cultural backgrounds are present in every major population and occupational group. The benefit to Canada of this new diversity is inestimable and provides a far richer background for local, national, and global relationships. Some groups have historically been underrepresented in certain professions, including nursing, in comparison with their representation in the population. Recognition of the contributions of different ethnic and cultural groups, including Aboriginal groups, to the cultural mosaic in Canadian society has been slow in coming.

Villeneuve (2002–2003) decried the fact that the majority of nurses in Canada remain white and female, a situation common in the health care professions. Gates (2007) found that the greater the perceived increased difference in status between a staff nurse and others in the setting, the weaker was the nurse’s intent to remain on the job. There has been pressure for the profession to enhance and improve programs in order to encourage nurses with minority cultural and racial backgrounds to enter programs and remain committed to their choices.

Nursing Education in Canada

In 1860, Florence Nightingale established a financially independent school of nursing in association with St. Thomas’s Hospital in London, England, with funds from the Nightingale Fund, a large sum of money from unsolicited donations to Nightingale in appreciation for her work in the Crimea.

Unfortunately, the educational model of the Nightingale school was missing from new hospital schools. This was

► BOX 3-2 Milestones in Canadian Nursing History

**Mary Agnes Snively, 1847–1933**

Born in St. Catharines, Ontario, Mary Agnes Snively was a teacher before she was a nurse. Upon graduation from the school of nursing at Bellevue Hospital, New York, in 1894, she was appointed Lady Superintendent of Nurses at Toronto General Hospital and director of the school of nursing. The school, founded along with the hospital three years earlier, was in a state of disorganization.

Students provided most of the nursing care at Toronto General Hospital at little cost to the hospital. Snively found no organized plan for classes or clinical experience, nor was there a residence (students were housed in various locations in the hospital). Written records of nursing care, medical orders, and patient histories were also lacking. Recruiting desirable applicants was difficult because students in the school faced so many hardships that parents were reluctant to allow their daughters to seek admission.

Snively rectified all these deficiencies. A residence was soon built; she developed a curriculum plan, including nursing theory and practice,

and she lengthened the education period to three years. By the end of her tenure in 1910, the Toronto General Hospital school was thriving as the largest school of nursing in Canada with hundreds of graduates, a full complement of students, and many more seeking admission. All parental skepticism had been overcome, and Toronto General Hospital served as a model for others across the country.

Snively achieved acclaim for her organizational work. She helped found the first nurses' alumnae association in Canada at Toronto General Hospital in 1894. She also attended the historic 1899 founding meeting of the ICN in London, England, and was elected first honorary treasurer of the ICN, even though Canada did not have the necessary national nursing association to become an ICN member at the time. In 1907, Snively established the Canadian Society of Superintendents of Training Schools of Nursing, and, recognizing that an organization that would include all nurses would be needed for Canada to become a member of the ICN, she was the driving force behind the 1908 founding of the Provisional Organization of the Canadian National Association of Trained Nurses (later the CNA), becoming its first president. She shepherded the entry of the fledgling Canadian organization to membership in the ICN and served later as ICN vice-president.

largely because the new schools had no financing and required students to provide nursing service to the hospital in return for their education and living expenses, which enabled hospitals to provide nursing services at minimal cost. The race to establish hospitals in the early 1890s was undoubtedly spurred on by the financial benefits of establishing associated schools of nursing. The financial advantage to the hospital of operating a school of nursing was clear, and this led to the need for hospitals to establish nursing schools to give them a competitive edge relative to other institutions to which paying patients might turn for care. Operating a training school also provided security against incurring financial loss if the number of paying patients was to drop at any point. Therefore, education of nurses became closely associated with hospitals at a developmental stage in the establishment of both hospitals and schools of nursing. The early hospitals were challenged financially because they did not charge poor patients. Services thus had to be of high enough quality to attract paying patients; a training school attached to a hospital ensured a higher standard of care than in one without a school (Young, 1994).

The First Canadian Nursing Schools

The first hospital diploma school in Canada, the St. Catharines Training School, opened in 1874 at the St. Catharines General and Marine Hospital. Admission standards were “plain English education, good character, and Christian motives” (*St. Catharines Annual Report*, cited by Healey, 1990). At that time, nursing was still considered an undesirable vocation for a refined lady in Canada, the only acceptable profession being teaching (Healey, 1990). Students learned chemistry, sanitary science, physiology, anatomy, and hygiene. They were taught to observe patients for changes in temperature, skin condition, pulse, respirations, and functions of organs and to report “faithfully” to the attending physician (Healey, 1990).

The School for Nurses at the Toronto General Hospital was established in 1881; Mary Agnes Snively was appointed

superintendent in 1884 (Box 3-2). Although work and living conditions were poor, Snively worked hard to improve the program. In 1896, she introduced a 3-year course with 84 hours of practical nursing and 119 hours of instruction by the medical staff (Gibbon & Mathewson, 1947).

In Montreal, after several unsuccessful attempts, the School for Nurses at the Montreal General Hospital was established in 1890 under the direction of Nora Livingston. Conditions were deplorable, but Livingston quickly made improvements. The popularity of the school increased rapidly. Livingston reported 169 applications in the first year, from which 80 students were accepted (Gibbon & Mathewson, 1947).

The move to establish hospital schools of nursing swept the country. The Winnipeg General Hospital initiated the first Training School for Nurses in 1887 in western Canada. A measure of its success was that 134 of its graduates served as nurses in World War I (Gibbon & Mathewson, 1947). By 1890, hospitals in Fredericton, Saint John, Halifax, and Charlottetown had opened schools. Vancouver General Hospital began a school in 1891, and in Alberta, a school was opened in Medicine Hat in 1894. By 1930, there were approximately 330 schools of nursing in Canada (CNA, 1968; Box 3-3).

The Impact of Nursing Organizations on Nursing Education

The Victorian Order of Nurses. At the same time that hospital training schools for nurses were being established, nurses began to advocate for improved educational standards and passage of legislation for their profession. Women's associations were instrumental in the public health care crusade in Canada and in the rise of nursing organizations. The National Council of Women under the presidency of Lady Ishbel Aberdeen, wife of the governor general of Canada, approved the formation of the Victorian Order of Nurses (VON) in 1898. Lady Aberdeen had conceived the idea of establishing the VON after she discovered the plight of

► BOX 3-3 Milestones in Canadian Nursing History

Jean I. Gunn, 1882-1941

Born in 1882 in Belleville, Ontario, Jean I. Gunn completed teacher training studies at Albert College in Belleville; her father was not in favour of her pursuing a career in nursing. Assisted by her mother, she went to New York to visit her sister and investigate nursing schools there. She then enrolled in the School of Nursing at Presbyterian Hospital, New York, graduating in 1905. After experience at her alma mater and in community nursing, Gunn was appointed

superintendent of nurses at the Toronto General Hospital in 1913. In this position, she was also responsible for the school of nursing.

Gunn recruited outstanding nursing administrators to assist her and became involved in provincial, national, and international health care and nursing organizations. She was a tireless worker and served with many organizations. Gunn was very supportive of the Toronto General Hospital alumnae association that in 1904 helped establish the Graduate Nurses' Association of Ontario (later the Registered Nurses' Association of Ontario) and pressed for legislation for the registration of nurses. She became secretary of the Canadian National Association of Trained Nurses in 1914 and president in 1917. She served on the executive of the National Council of Women and became very involved in the Canadian Red Cross Society, for which she chaired a committee on surgical dressings during World War II. In this role, she oversaw the production of millions of dressings by female civilian volunteers.

Nurses were in short supply during this time. With most men in the armed forces, many industrial jobs were now open to women and at wages far surpassing those of nurses. In 1917, Gunn pressed for the establishment of a permanent cadre of trained nurses for national service. She continued to work for the registration of nurses, which came to fruition in Ontario in 1922.

Gunn advocated for nursing and nurses on many fronts. She castigated hospital boards for reviewing costs of hospital services while

ignoring the savings that accrued from educating a nurse. She was passionately interested in improving standards of nursing education. She decried the exploitation of nurses in schools of nursing and worked with other nursing leaders to establish the Weir study of nursing and nursing education, jointly sponsored by the CNA and the Canadian Medical Association. The 1932 Weir report confirmed the deficiencies that she and other nursing leaders had publicized for so long, and she campaigned for the implementation of its recommendations.

Gunn also envisioned university degree programs in nursing and in 1914 arranged for the Department of Social Service at the University of Toronto to give lectures to third-year Toronto General Hospital students. In 1917, a course in chemistry taught by university instructors was implemented. The following year, field experience in public health nursing was introduced, and Gunn organized centralized lectures among Toronto schools of nursing held at the University of Toronto.

Gunn is perhaps best remembered for her work establishing the Nurses' War Memorial, which recognized the service of military nurses during World War I. She lobbied politicians and other health care organizations extensively and raised money from 10,000 nurses and their organizations from all over Canada. The result was a bas-relief sculpture in white Carrara marble that was unveiled in 1924 in a prominent position in the Centre Block of the Parliament Buildings, located in the Hall of Honour, separating the House of Commons from the Senate. In 1932, Gunn was responsible for having the crest of the CNA added to the sculpture.

In recognition of her outstanding service to nursing and health care throughout her life, Gunn received a number of honours in her final years, including a King's Jubilee Medal in 1935 and a Doctor of Laws degree from the University of Toronto in 1938. Jean Gunn was a leader among leaders in nursing and an individual who was able to inspire nurses to contribute to the common good.

women in western Canada who had to give birth in remote locations with no assistance. The formation of the VON signified a professional standard of education for Canadian nurses that recognized the need not only for altruism and compassion but also for nursing knowledge (Figure 3-4).

The International Council of Nurses. Nurses from around the world were beginning to form organizations, inspired by the leadership of women such as Ethel Gordon Fenwick. Editor of the *British Journal of Nursing*, she attended the 1893 Congress of Charities, Corrections, and Philanthropy in Chicago, where she spoke of British struggles to achieve registration for nurses. Her North American colleagues had similar concerns. After the congress, they formed the American Society of Superintendents of Training Schools for Nurses of the United States and Canada, later to become the National League for Nursing Education, whose goal was to raise standards of nursing education. Soon afterward in 1896, the Nurses' Associated Alumnae of the United States and Canada was formed, becoming the American Nurses Association in 1911. A major goal was to secure legislation to differentiate between trained and untrained nurses (CNA, 1968).

In 1899, Bedford Fenwick founded the **International Council of Nurses (ICN)**, with Britain, Germany, and the

United States as member organizations. Nations without national nursing organizations could not become members. Although Canada did not yet have a national nursing organization, Mary Agnes Snively was elected the first honorary treasurer of the ICN in 1899 (CNA, 1968). This international organization of nurses that emerged from nurses' concerns about registration has remained strong over more than a century and continues to champion important nursing and health care issues (Lynaugh & Brush, 1999).

The Origins of the Canadian Nurses Association and Provincial Nursing Associations

The Canadian Society of Superintendents of Training Schools for Nurses was formed in 1907. The next year, the Provisional Society of the Canadian National Association of Trained Nurses (CNATN) was formed. Mary Agnes Snively served as founding president of both organizations (CNA, 1968). Membership in this new national organization was through affiliated societies in the provinces. At the ICN meeting in 1909, Canada became a full-fledged member of the organization. Later, the CNATN streamlined its organization when registration of nurses was established through legislation in each province. Its name was changed to the *Canadian Nurses Association*

Figure 3-4 Victorian Order of Nurses badge, Edmonton, Alberta, 1927. **Source:** Glenbow Archives, NC-6-12085.

(CNA) in 1924, and it became a federation of provincial associations in 1930.

The struggle for women's rights helped nurses to secure laws to regulate their profession. Nurses formed provincial nurses' associations and sought legislation that would set educational standards and improve nursing care. The first province to gain legislation was Nova Scotia, where a voluntary registration act was passed in 1910. It also allowed nongraduate nurses to register. Initial acts passed in other provinces contained more restrictive standards. Admission criteria and curricula were set for nursing schools, as were rules governing the registration and discipline of practising nurses.

All provinces and two territories eventually secured mandatory registration, requiring that all practising nurses register with the regulatory body approved by the provincial nursing act (Canadian Institute for Health Information, 2006). The distinguishing feature of mandatory rather than permissive legislation is a statute containing a definition of the scope of nursing practice and protecting the use of the title of *registered nurse*. Permissive legislation only protects the title of *registered nurse* (Wood, 2011). Licensure laws are designed to protect the public against unqualified and incompetent practitioners.

The First University Programs

The devastating consequences of World War I and the influenza pandemic of 1918 led to support for public health programs and new patterns of health care delivery. Community health care was promoted, and nurses were seen as central participants who needed university-level education. To this end, the Canadian Red Cross Society awarded grants to a number of Canadian universities to develop postgraduate courses in public health nursing: University of Toronto, McGill University, University of British Columbia, University of

Alberta, Dalhousie University, and University of Western Ontario (Canadian Red Cross Society, 1962).

The first Canadian undergraduate nursing degree program was established at the University of British Columbia in 1919, with Ethel Johns as director. The operating costs of the new department were to be borne by the hospital, an incentive for the university to support the program. The program was nonintegrated—that is, “the university assumed no responsibility for the two or three years of nursing preparation in a hospital school of nursing” (Bonin, 1976, p. 7).

Several new five-year, nonintegrated degree programs began at Canadian universities in the 1920s and 1930s: the University of Western Ontario, the University of Alberta, l'Institut Marguerite d'Youville, the University of Ottawa, and St. Francis Xavier University.

Health Care and Educational Reform

The Weir Report

Program quality became an important concern from the time of the rapid development of nursing education programs in hospitals. The system of nursing education that evolved placed a low priority on the education of women in society. To this day, there are strong elements of a feminist struggle against traditional views on the education of women in the drive to improve standards and quality in nursing education. Nursing students were exploited in the apprenticeship system of nursing education that developed in hospital-based diploma nursing programs. Ending exploitation and ensuring that the goal of nursing programs was the education of the student became causes championed by nursing educators over most of this century. In the 1920s and 1930s, nursing leaders argued for a standard curriculum and for allowing programs to be operated only by hospitals that had enough beds to ensure that schools had the clinical and material resources to support a strong nursing education program. In 1932, Dr. George Weir reported the results of the first national study of nursing education (Weir, 1932). This study was commissioned jointly by the CNA and the Canadian Medical Association (CMA) and confirmed nursing educators' worst fears, that conditions in nursing schools were deplorable, that the health of students was being compromised, and that education was secondary to hospital service as a priority in schools (CMA et al., 2004).

The Royal Commission on Health Services of 1964

Preparing a sufficient number of graduate nurses became the rallying cry of the 1940s, both during the war and throughout the late 1940s and the 1950s. In the expansionist years of the 1960s, nursing leaders called for better prepared faculty in schools and for quality and standards as priorities in nursing education programs. Existing nursing-degree programs began to expand, and new programs emerged in other universities. The basic integrated degree model became the program of choice by the 1970s, as the Royal Commission on Health Services (1964) castigated universities for granting degrees for work over which they had no control, namely the three-year apprenticeship-based hospital diploma program that was “sandwiched” between two years of university study in most nonintegrated baccalaureate degree programs.

The demand for the transfer of responsibility for nursing education to the general educational system that had begun in earnest with the Weir Report of 1932, was heightened by experiments with two-year programming in the 1950s, when the

Demonstration School was established in association with the Metropolitan General Hospital in Windsor, Ontario. Made possible by a grant from the Canadian Red Cross Society, this experimental school was deemed successful in an evaluation of the project (Lord, 1952). The rallying cry of the reformists began to be heard in the 1960s, and the movement to separate nursing education programs from the authority of hospitals began in earnest. Two-year programs in nursing began to appear, and Ontario, Quebec, and Saskatchewan developed a system of diploma education based entirely in community colleges. This transfer of diploma programs to the general education system was in full swing when the Alberta Task Force on Nursing Education recommended in 1975 that all new graduates be prepared at the baccalaureate level before entering professional practice. The position was endorsed by the Alberta Association of Registered Nurses in 1976 and was approved by the CNA in 1982 with a target date of the year 2000. By 1988, when the New Brunswick Association of Registered Nurses endorsed the position, all provincial associations had declared their support (CNA, 1991). Most provincial and regulatory bodies have now made the baccalaureate degree a requirement for the practice of nursing (CNA & Canadian Association of Schools of Nursing, 2004).

Canadian Nurses Association Reports

As late as 1965, the CNA found that 105 out of the 161 hospital schools of nursing participating in the School Improvement Program reported that the selection of clinical assignments was not based on the students' educational needs, but on the service needs of the patient care units (CNA, 1965). Many persistent problems were identified by those who surveyed nursing education in Canada. Helen K. Mussallem found that hospital schools of nursing used their students as a workforce, that hours on duty were too long, that nursing instruction in the classroom was limited and insufficient, and that teaching personnel were ill-prepared and too few in number. The entrenchment of the hospital-based system of nursing education carried with it certain features that nurses considered to be undesirable, and improving standards of education in the schools thus became a primary preoccupation of the professional association for many decades.

Direct clinical experience was the method of choice for educating students to care for hospital patients. Since service took priority over education in the hospital schools, clinical experiences tended not to be planned with the learning needs of the student in mind. Thus, students often performed tasks repetitively and did not have the needed instruction to assist them to understand the complexities of the care they were expected to give. In schools of nursing associated with small hospitals, the range of experience needed for a well-rounded educational experience was just not available. In other schools, students were expected to work very long hours to provide the staff to meet the service requirements of the hospital, and all too often, this had an adverse effect on their health. The system of nursing education embodied in the hospital school had many proponents who argued the merits of apprenticeship as a form of learning. However, as Paul has noted, "for most of the century, the lack of nursing instructors and of other graduate nurses on patient care units meant that there were few role models for students for observation, questions and general discussion. In most cases senior students were left in charge of teaching junior students and this with very limited supervision" (Paul, 1998, pp. 133–134). It can be argued that nursing students were

not under a true apprenticeship program since there were no masters guiding the novices (Chapman, 1969, p. 528).

Baccalaureate Entry-to-Practice

The entry-to-practice position stipulated that all new graduates in nursing must be qualified at the baccalaureate level when they entered the professional practice of nursing. The year 2000 was initially set as a goal for implementation. Although this position originally was put forward by a government committee in Alberta in 1975, it became a highly valued goal of the nursing profession across the country in less than a decade. When nursing organizations put forward their statements supporting the position, they hoped that the position would become a reality by the expected date. At the same time, they recognized from the outset that achieving the position would be unlikely by the year 2000. It was simply a target date to assist with moving toward the goal. Contrary to what many believed, the position never had any kind of legal or political mandate. The reluctance of provincial governments over two decades to endorse the baccalaureate standard for entry to the practice of nursing reflected the fact that equality in education for women in nursing did not come easily. The announcement by the Premier of New Brunswick in 1992 that the baccalaureate degree should be a prerequisite to the practice of nursing was the first such endorsement by a first minister of a Canadian province (Nurses Association of New Brunswick, 1992). Implementation of the baccalaureate standard occurred first in Prince Edward Island in 1992, but would not have been the case without the strong support of its provincial government. Slowly but surely other provincial governments endorsed the position and made adjustments in the capacity of their provincial degree-granting nursing education programs to accommodate all students studying nursing at the undergraduate level. Although all provinces have now achieved baccalaureate entry to practice, the incredible struggle to achieve this goal by nurses should be recognized.

Influence of Periods of Social Upheaval on Nursing

Public Health, Military Conflicts, and the Emergence of University Nursing Education

The struggle for social equality, which became a rallying cry for women in the first quarter of the twentieth century, also took hold on the prairies, where the energies of women and men alike were required to work the land and to provide the services that were necessary in a frontier milieu. Women in western Canada became seriously involved in commenting on needs in health and education and developed organizations to put forward their ideas. Five Alberta women, Nellie McClung, Emily Murphy, Henrietta Muir Edwards, Louise McKinney, and Irene Parlby, pressed forward with "the persons case," petitioning the Supreme Court of Canada and ultimately the Privy Council of Great Britain to declare that women were "persons" and as such could be elected to public office. Education had long been viewed by women as a means of surmounting perceived inequities in society. This was also true in nursing as confirmed by Baumgart and Kirkwood (1990): "Nursing within the university metaphorically represents the struggle of women to have their experience and knowledge validated and legitimized, and their professional expertise recognized as a university discipline" (p. 510).

The impetus for the introduction of nursing programs to the university was the perceived need for additional and highly capable nursing staff for public health work. In the aftermath of World War I, the impact of casualties and disability led to new value being placed on promoting and maintaining health. The devastating consequences of the war along with those of the worldwide influenza epidemic of 1918 and 1919 led to support for public health programs and new patterns of health care delivery to prevent disease and improve the health and well-being of the Canadian populace. The health of mothers and children was seen as particularly critical to the nation because nurturing the health of the young was believed to raise the likelihood that the adult population of the future would be healthier than that of the past. In the new movement to promote health in the community, nurses were seen as central players with a need for additional, university-level preparation for their work.

Because of the above issues, the Canadian Red Cross Society became a partner in establishing the League of Red Cross Societies and in planning an international program for peace-time activity in public health: "It was decided that there should be a great worldwide public health organization to help bring up the standards of physical and mental fitness of the world . . . the promotion of health, the prevention of disease and the mitigation of suffering throughout the world" (Gibbon & Mathewson, 1947, p. 342). This organization served as a catalyst for the development of university programs in nursing. A national committee was formed with representatives from the Canadian National Association of Trained Nurses, the Canadian Red Cross Society, and the St. John Ambulance Association, and they endorsed the following resolutions on September 10, 1919:

That the Central Council of the Canadian Red Cross Society should approach the universities with a view to the establishment of Nursing Departments, and that this action should be followed up by the Provincial Branches which should receive copies of the correspondence between the Head Office and the university; . . . That the adoption of the above policy should entail grants-in-aid to the universities establishing such courses. . . . (Canadian Red Cross Society, 1962, p. 96)

This was followed by three-year grants from the national organization of the Canadian Red Cross Society to six Canadian universities for the development of postgraduate courses in public health nursing. The Red Cross Society first directed its efforts to providing funds for the provision of facilities for postgraduate instruction in public health nursing "by subsidizing special courses for three years at the Universities of Toronto, McGill, British Columbia, Alberta, and Dalhousie" (Gibbon & Mathewson, 1947, p. 342). A Red Cross grant to the University of Western Ontario came from the provincial rather than the national organization.

When the first course in public health nursing was offered at the University of Alberta in 1918 shortly after the establishment of the Public Health Nursing Service, it became the first nursing program offered by a university in Canada: "The appointment of Public Health Nurses was a prominent item . . . on the above mentioned programme. Miss Christine Smith being appointed as superintendent, and four graduate nurses. Misses Sargent, Davidson, Clark and Thurston were engaged as field nurses. These, after receiving special training at the University, and from specialists along public health lines, were

placed at different points through the province" (Department of Public Health Nursing, 1918).

This course was of two months' duration and began on April 1, 1918 (Stewart, 1979, p. 10). A second course was held in 1919; a third in 1921. The *Public Health Nurses' Act*, passed in 1919, formalized the program and designated the University of Alberta as the institution offering the course, specifying that it would lead to a certificate or diploma, and authorized the graduate to "affix after her name the letters 'PH'" (Revised Statutes of Alberta, 1919, p. 793). The Act provided that

(1) There shall be established in connection with the Provincial University a special course of study for nurses. (2) The said course shall include sanitation, personal hygiene, bacteriology, public health, examination of eye, ear, nose throat and teeth, the pre-natal period, infant welfare, child welfare, inspection and instruction of school children, communicable diseases, preventive medicine and methods, and such other studies as from time to time the Senate of the University may prescribe. (Revised Statutes of Alberta, April, 1919, Section 38, p. 793)

From the Depression to the Post-World War II Years

The Great Depression "brought unemployment and hardship to nurses" (Allemang, 1974, p. 172). Patients could no longer afford to employ private-duty nurses, which had been the most promising area of employment for graduate nurses (Gunn, 1933). During the Depression, Canadian universities faced reduced revenues, staff layoffs, and difficult working conditions. The Depression was especially hard on McGill University, which depended on funds from private sources. During the Depression, raising private funds became next to impossible. Leaders of McGill's nursing school had fought unsuccessfully for years for a degree program. Once the university's finances began to deteriorate, the board of governors threatened to close the school altogether. The school's director, Bertha Harmer, gave up her salary, the faculty bought books for the library, and nursing alumnae groups all over the country raised funds to ensure the survival of the McGill nursing school (Tunis, 1966).

During World War II, health education again became a priority as doctors and nurses were needed to care for military personnel, as well as civilians. Nurses who held critical positions as administrators, supervisors, teachers, and public health nurses were recruited for military service and left their positions. A shortage of nurses soon developed. During and after the war, a new interest in nursing education led to increased external university funding, more scholarships and bursaries from private foundations, the growth of existing schools, and the founding of new programs between 1941 and 1949. Programs were initiated at Queen's, McMaster, Manitoba, Mount Saint Vincent, and Dalhousie universities. At McGill, new funds flowed in, and in 1944, supporters of the school were rewarded with a five-year nonintegrated degree program. Most nonintegrated programs offered a two- to three-year apprenticeship-based hospital diploma program sandwiched between two years of university study. The nonintegrated degree pattern with its stepladder approach to nursing education was well established, and the hospital programs on which this approach depended had been entrenched for many years. However, the new interest in nursing education led to exciting innovations. In 1942, the University of Toronto introduced an integrated basic degree program. Under the leadership of Edith Kathleen Russell (see Chapter 4),

courses in arts and sciences were taught concurrently with nursing courses to enhance student development. Also, university instructors supervised student clinical practice in the health care agencies. Four years after the introduction of the University of Toronto basic degree program, a second basic degree program was developed at McMaster University under Gladys Sharpe's direction.

Emerging From Economic and Military Crises

In the 1960s, existing nursing degree programs expanded, and new programs emerged in other universities. The first master's degree program in nursing was established at the University of Western Ontario in 1959, followed in the 1960s and 1970s by similar programs in universities across the country. In 1962, the Canadian Nurses Foundation was established as an entity separate from the CNA, to provide scholarships, bursaries, and fellowships for graduate study in nursing.

Nursing schools' financial dependence left them at the mercy of hospital administrators. As noted above, the lack of instructors and nurses on patient wards meant that it was senior students who were typically given the responsibility to teach junior students (Paul, 1998). Many authorities have suggested that this was not a true apprenticeship model because it lacked the "master craftsman" to guide the students (Chapman, 1969).

Nursing leaders called for better faculty preparation, more integrated programs, and more university-based opportunities for students, such as student placements and increased enrollments. The movement to separate nursing education programs from the authority of hospitals began in earnest, particularly after the aforementioned studies on nursing education, conducted in the early 1960s, identified persistent problems.

Universities resisted introducing basic integrated degree programs because of the costs associated with the low student-teacher ratios required for clinical nursing. It was cheaper for them to let hospitals finance clinical education, but this meant that universities granted degrees for work over which they had no control. In 1964, the Royal Commission on Health Services castigated universities for this practice. By the late 1960s, the basic integrated degree program modelled on the program at the University of Toronto finally became the prototype for the establishment of integrated programs in nursing in universities across the nation.

Throughout the 1970s and 1980s, university faculties and schools of nursing developed research resources so that they could offer graduate programs first at the master's level and then at the doctoral level. The first doctoral nursing program was established at the University of Alberta Faculty of Nursing on January 1, 1991, and others quickly followed.

The CNA has developed a position statement on promoting nursing history (CNA, 2008), noting that learning from the lessons of history is "critical to advancing the profession in the interests of the Canadian public." This statement outlined the responsibilities of nurses across the whole gamut of roles and settings to promote nursing history.

Nursing Education Today

With continuing expansion of health care knowledge and technology, beginning practitioners require a broad educational foundation. New curricula and collaborative baccalaureate programs across the country attest to the profession's commitment to maintaining high standards of health care and responding to society's changing health care needs. The

Internet, computerized learning programs, shared faculty through teleconferencing, and weekend and evening courses provide practising nurses with many options to complete degrees. The CNA's nursing portal, NurseOne, has made database information available to nurses across the country. Some universities have innovative programs at the baccalaureate level, including accelerated programs in which candidates hold a baccalaureate degree in other fields. Baccalaureate programs, master's degree programs, and some courses in doctoral programs are also offered through distance education.

Standards for nursing education are monitored by each province to ensure that educational programs are of appropriate quality and respond to changes in health care. As professionals, nurses must acquire, maintain, and continuously enhance the knowledge, skills, attitudes, and judgement necessary to meet patient needs in an evolving health care system. The responsibility for educational support for competent nursing practice is shared among individual nurses, professional nursing organizations, educational institutions, and governments (Wood, 2011).

The need for nurses with graduate degrees is rising, along with the need for research. A master's degree in nursing is necessary for nurses seeking positions as clinical nurse specialists, nurse practitioners, nurse administrators, or nurse educators. Most master's programs in Canada now offer a concentration in advanced nursing practice for clinical nurse specialists and nurse practitioners. This provides advanced preparation in nursing science, theory, and practice, with emphasis on evidence-informed clinical practice. Nurses with doctorates can undertake research that advances knowledge and evidence-informed practice in clinical settings (see Chapter 6). This research enhances the quality of nursing care and improves Canadians' health outcomes. Today, there are 30 master's programs and 12 doctoral programs in nursing in Canada.

Conclusion

Organized nursing has been a part of the social setting in Canada since the early days of the European settlement at Quebec, a period of more than three and a half centuries. The first nurses who came to found hospitals and provide care for Aboriginal people and settlers were motivated by altruism and serve as excellent role models for nurses today. Altruism, a hallmark of any profession, remains an important characteristic of the nursing profession despite vast differences between health care settings of the early days and those of today.

A fundamental and guiding principle of the French-Canadian hospitals that survived largely intact into the twentieth century was that care was available to all people regardless of their background, status in life, or ability to pay. This continues to be a principle for which nurses, through their **professional organizations**, groups with informal and/or legal authority to represent the nursing profession, have argued determinedly in national debates on the nature and continuing direction of Canada's national health care insurance program. In the presence of pressure to reshape Medicare, nurses have continued to strongly resist calls for privatization of more aspects of the health system. They have also repeatedly called for all health care providers to be remunerated on a salary or contract basis (Ross-Kerr, 2011).

Multidisciplinary teams are an integral component of the health care organization in the community. However, nurses are the primary health care providers both in home care and

in community health settings. Thus, expanded and enhanced educational systems for nurses that incorporate knowledge and skills for community health and home care nursing are essential to meet the health needs of the populace today.

The transformation of the nursing profession and of the educational programs that have supported it since the nineteenth century has been truly remarkable. Despite monumental obstacles, nurses have demonstrated the value of their service, the integrity of their goals, the quality of their educational programs, and the strength of their commitment. Although developments through the twenty-first century are as yet unknown, it is certain that the nursing profession will continue to evolve in the interest of providing a high quality of nursing care to the populace.

❖ KEY CONCEPTS

- Nursing has responded to the health care needs of society, influenced over time by economic, social, and cultural factors.
- Nursing in Canada is rooted in the traditions of good nursing that developed in New France.
- Florence Nightingale revolutionized nursing as an acceptable profession for women as lay nurses in the late 1800s and early 1900s.
- The development of a system of nursing education in Canada emerged from the early nursing sisterhoods and from schools of nursing associated with hospitals.
- Baccalaureate entry to practice has been fully implemented in Canada.
- Basic nursing education is acquired in college, collaborative college-university, or university programs.
- The ranks of the profession are moving toward gender balance and a racial, ethnic, and cultural mix that reflects the Canadian population.

❖ CRITICAL THINKING EXERCISES

1. Explain the importance of Florence Nightingale's work to establish nursing as a profession.
2. Identify some of the enduring values that have emerged from the history of nursing in Canada.
3. Observe various levels of nursing practice, such as a staff nurse, nurse practitioner, and nurse educator. Identify similarities and differences in their roles and educational preparation.
4. Outline some career objectives for yourself after completing your nursing program. Think about what you want to do as a professional nurse, and then outline strategies for achieving these goals.

❖ REVIEW QUESTIONS

1. The founder of modern nursing is
 1. Hippocrates
 2. Florence Nightingale
 3. Jeanne Mance
 4. Mary Agnes Snively
2. The founder of the Sisters of Charity of Montreal, which later became known as the Grey Nuns, is
 1. Marie Rollet Hébert
 2. St. Vincent de Paul
 3. Marguerite d'Youville
 4. Lady Ishbel Aberdeen

3. The first doctoral nursing program in Canada was established in
 1. 1890
 2. 1933
 3. 1975
 4. 1991
4. Nurse practitioners in Canada
 1. Work in university health settings
 2. Are able to function independently
 3. Are licensed under nursing legislation in jurisdictions
 4. Function as unit directors in health agencies
5. Nursing has a code of ethics that professional registered nurses follow, which
 1. Defines the principles of nursing care
 2. Ensures identical care to all patients
 3. Protects the patient from harm
 4. Improves self-health care
6. Which of the following is *not* a function of a professional nursing organization?
 1. Regulating registration and professional conduct
 2. Monitoring unregulated care providers
 3. Collaborating with other health care organizations on matters of mutual interest
 4. Establishing standards of education and professional practice
7. The practice of nursing is regulated by
 1. The CNA
 2. Nursing practice acts
 3. Best practice guidelines
 4. Hospital administrators
8. Except for Ontario and Quebec, minimum standards for nursing education are set by
 1. The nursing school
 2. The provincial or territorial nursing association
 3. The Canadian Nurses Association
 4. The Canadian Nurses Federation
9. A role of a nursing union is to
 1. Devise ethical standards to guide practice
 2. Set the standards of practice for nursing
 3. Represent nurses in bargaining for new contracts
 4. Carry out registration and licensure

Community Health Nursing Practice

Written by Kaysi Eastlick Kushner, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Explain the relationship between community health nursing and primary health care.
- Discuss the roles and functions of the community health nurse.
- Differentiate between public health nursing and home health nursing.
- Explain the characteristics of clients from vulnerable populations that influence a nurse's approach to care.
- Describe the standards, competencies, roles, and activities important for success in community health nursing practice.
- Describe elements of a community assessment.

key terms

Community, p. 44	Population health, p. 45
Community-based nursing, p. 45	Primary health care, p. 44
Community health nursing, p. 44	Public health, p. 45
Community health nursing practice, p. 44	Public health nursing, p. 45
Empowerment, p. 44	Public health principles, p. 45
Harm reduction, p. 49	Social justice, p. 44
Home health nursing, p. 45	Vulnerable populations, p. 47
Population, p. 44

Today's health care climate is rapidly changing in response to economic pressures, technological and medical advances, and client participation in health care. As a result, many clients are receiving care in the community rather than in hospital. There is a growing need to deliver health care where people live, work, and learn (Community Health Nurses of Canada [CHNC], 2011). Community health nursing care focuses on health promotion and protection, disease and injury prevention, and restorative and palliative care. The goals of community health nursing are to keep individuals healthy, encourage client participation and choice in care, promote health-enhancing social and physical environments, and provide in-home care for ill or disabled clients.

Promoting individual and community health has always been key to the holistic practice of nursing. In the 1730s, the Grey Nuns were established as Canada's first community nursing order. More than a century later, in England, Florence Nightingale articulated a nursing

► BOX 4-1 Milestones in Canadian Nursing History

Kate Brighty Colley, 1883–1985

Born in England in 1883, Kate Brighty immigrated with her parents to Nova Scotia at the age of three years. She graduated from the Royal Alexandra Hospital School of Nursing in Edmonton in 1917, after which she enlisted with the Canadian Army Medical Corps in Calgary.

After completing a course in public health nursing at the University of Alberta in 1919, Brighty was one of the first nurses to be appointed to the staff of the new Alberta Department of Public Health. Soon afterward, the Alberta Department of Agriculture engaged her to teach home nursing, bedside care, and hygiene in Grande Prairie.

In the same year, Brighty was appointed matron of the second municipal hospital in Alberta, the Mission Hospital at Onoway. Because there were no physicians in the region, she and her two employees staffed the hospital and visited rural patients on horseback. In 1923, she returned to the Department of Public Health to establish a district nursing centre at Buck Lake, southwest of Edmonton, an area that had no roads at the time, and then another centre, farther north at Wanham, near the Peace River. Here, she travelled by cutter to assist women in labour and those who were ill.

In 1925, Brighty took a postgraduate course in public health nursing at Columbia University, New York. Upon her return to Alberta in 1928, she was appointed director of the Department of Public Health Nursing. Her responsibilities were expanded a year later to include the post of inspector of hospitals. In her new post, Brighty established a number of new district nursing centres. As a former district nurse, she understood the problems these nurses faced, and she travelled widely to visit staff. She expanded the health education program and gave radio talks on health, hygiene, nutrition, and child welfare. These broadcasts were important to residents of remote areas, where little formal health care was available.

Brighty was active in the Alberta Association of Registered Nurses (AARN) and, in 1936, was elected president of the organization. She wrote the first history of nursing in Alberta, the *AARN Blue Book* (Brighty, 1942).

After 24 years of service to the Department of Public Health Nursing, she retired in 1943 to Vancouver Island, and in 1970, she published *While Rivers Flow: Stories of Early Alberta*, experiences and short stories based on her public health nursing practice.

► BOX 4-2 Milestones in Canadian Nursing History

Edith Kathleen Russell, 1886–1964

Edith Kathleen Russell was born in Windsor, Nova Scotia, in 1886. She entered the Toronto General Hospital School of Nursing in 1915 and, after graduating, worked with the Department of Public Health in Toronto. In 1920, the Department of Public Health Nursing at the University of Toronto was established, and Russell was appointed its first director.

Russell recognized the great need for improved nursing education. At the time, the norm was an apprenticeship system in hospital schools, in which students, rather than graduate nurses, fulfilled nursing tasks. The primary focus of the hospital school system was not education but hospital service; the incentive was mainly financial. Although public health nursing was her department's original focus, Russell turned her attention to hospital nursing. She gained the

support of the University of Toronto and the Rockefeller Foundation for an experiment in basic nursing education and obtained a grant of more than \$250,000. This was at the height of the Great Depression, when other university schools were fighting for their very existence.

Russell's diploma program, begun in 1933, prepared nurses for hospital and public health nursing. In 1942, her program evolved into an integrated basic degree program controlled by the university, in which clinical practice was obtained at affiliated hospitals under supervision of university instructors. This program was the first of its kind in Canada and was hailed throughout the world as an important new system of nursing education. Today, hospital-based schools of nursing have largely given way to schools in the general educational system, either in community colleges or in universities, and most provinces are adopting the degree as the basic credential for nursing practice. Edith Kathleen Russell is widely recognized as the architect of the integrated degree nursing program.

philosophy grounded in knowledge of environmental conditions. By the end of the century, the Victorian Order of Nurses was providing in-home nursing, often in outpost and remote regions. After World War I, community nursing responsibilities "extended to screening programs to detect disease at early stages, to helping to maintain a healthy environment, and to providing nursing care" (Ross-Kerr, 2011, p. 25).

Canadians such as Kate Brighty Colley (Box 4-1) and Edith Kathleen Russell (Box 4-2) pioneered community and public health nursing in Canada. Today, nursing is leading the way in assessing, implementing, and evaluating public and community-based health services needed by clients. Community health nursing is essential for improving the health of the general public.

Promoting the Health of Populations and Community Groups

Nurses practising in the community face many challenges in promoting the health of populations and community groups. A **population** is a collection of individuals who have in common one or more personal or environmental characteristics (Maurer & Smith, 2005). Examples of populations are Canadians inclusively and, more specifically, older adults or a cultural group such as Aboriginal peoples. A healthy population is composed of healthy individuals, and the health status of individuals is considered an overall aggregate that reflects an average or general health status. To determine a population's health status, individual characteristics (such as occurrence of illness, disability, and death; lifespan; education; and living conditions) are considered. A **community** is a group of people who share a geographic (locational) dimension and a social (relational) dimension (Edwards & Moyer, 2000; Laverack, 2004). The social dimension—which comprises individual relationships, interactions among groups, and shared characteristics among members—distinguishes a community from a population. Examples of communities are geographic groupings (e.g., neighbourhoods) and shared-interest groups (e.g., women's health networks). A healthy community consists of healthy individuals engaged in collective relationships that create a supportive living environment. Both individual and community characteristics are used to determine community health status. **Key characteristics of a healthy community** include a collective capacity to solve problems; adequate living conditions; a safe environment; and sustainable resources such as employment, health care, and educational facilities.

Community Health Nursing Practice

The scope of **community health nursing practice** includes population health promotion, protection, maintenance, and restoration; community, family, and individual health promotion; and individual rehabilitation or palliative care. Community health nurses “promote, protect, and preserve the health of individuals, families, groups, communities, and populations” (CHNC, 2011, p. 4). Practice involves coordinating care and planning services, programs, and policies by collaborating with individuals, caregivers, families, other disciplines, communities, and governments. Practice combines knowledge of nursing theory, including the metaparadigm concepts of person, health, nursing, environment, and social justice as a theoretical foundation, social sciences, and public health science (CHNC, 2011). **Social justice** is rooted in notions of societal (social) responsibility and fairness (justice). “Social justice is the equitable, or fair, distribution of society's benefits, responsibilities and their consequences. It focuses on the relative position of social advantage of one individual or social group in relation to others in society as well as on the root causes of inequities and what can be done to eliminate them” (CNA, 2010, p. 13). Social justice encompasses equity, human rights, democracy and civil rights, capacity building, just institutions, enabling environments, poverty reduction, ethical practice, advocacy, and partnerships (CNA, 2010).

Community health nursing includes public health nursing, home health (community-based) nursing, and community mental health nursing, as well as a variety of other specialties such as street health and parish nursing (CHNC, 2011; see also

Stamler & Yiu, 2011, and Stanhope et al., 2011, for in-depth descriptions of community health nursing roles in Canada). Occupational health nursing has emerged as a distinctive specialized practice, although it is arguably within the inclusive focus of community health nursing.

The community health nursing focus is broad, emphasizing both the community's health and direct care to subpopulations within that community. By focusing on subpopulations, the community health nurse cares for the whole community and considers the individual to be one member of a group. The practice focus of different specialties within community health nursing varies: for example, home health nurses focus on individual clients, then broaden their view to consider family and community, whereas public health nurses more often shift from a broad view of populations to narrow their focus to specific vulnerable groups or families (CHNC, 2011).

Regardless of specific role, function, or setting, community health nursing practice is guided by values of caring, principles of primary health care, multiple ways of knowing, individual and community partnerships, empowerment, and social justice (CHNC, 2011). **Primary health care** focuses on education, rehabilitation, support services, health promotion, and disease prevention. It involves multidisciplinary teams and collaboration with other sectors, as well as with secondary and tertiary care facilities (see Chapter 2). Primary health care principles guide community health nurses to use empowerment-based models of community practice (Chalmers & Bramadat, 1996; CHNC, 2011). **Empowerment** may be most simply described as a psychological, cultural, social, or political process by which people, individually and collectively in organizations and communities, exercise their ability to effect change to enhance control, quality of life, political effectiveness, and social justice (Canadian Public Health Association [CPHA], 2010). Empowerment is both an outcome and a process by which that outcome is achieved. Empowerment exists in dynamic power relations among people, which from a health promotion perspective are expressed as “power with” rather than “power over” relations (Labonte, 1993). Although empowerment is commonly conceptualized as a process continuum from personal to small group to community organization to partnership to social and political action (Laverack, 2004), Labonte's holosphere (Venn diagram) better depicts the interrelated and nonlinear dynamic of empowering processes in practice. Criticisms that empowerment is often misinterpreted as increasing individual responsibility but overlooking power and control (Cooke, 2002) highlight the importance of action to ensure that adequate resources are available for individuals and for groups and communities collectively. Such action would be grounded in ethical commitment to inclusion, diversity, participation, social justice, advocacy, and interdependence as a complementary foundation to the Canadian Nurses Association (CNA) *Code of Ethics* intended to guide all nursing practice (Racher, 2007).

Empowerment-based skills of client advocacy, communication, and the design of new systems in cooperation with existing systems help make community health nursing practice effective. The Canadian Community Health Nursing Practice Model (CHNC, 2011) articulates how community health nursing care encompasses actions aimed at illness care; illness, disease, or injury prevention; and health promotion. Nursing actions are guided by approaches oriented to capacity building, participation, collaboration, inclusiveness, equity, social justice, and advocacy. These actions complement one another,

even as their underlying aims, approaches to care, and perceptions of clients may differ.

Community health nursing practice requires a distinct set of skills and knowledge. Expert community health nurses understand the needs of a population or community through experiences with individuals, families, and groups. They think critically in applying a wide range of knowledge to find the best approaches for partnering with their clients. In 2006, the CNA introduced a community health nursing certification (CNA, 2006). Certification confirms practitioner competence in the specialty, recognizes nurses who meet the national standards of the specialty, and promotes excellence in nursing care for the Canadian population (see CHNC [2011] and CNA [2006] for standards and certification procedures).

Public Health Nursing

Public health nursing merges knowledge from public health science, social sciences, and primary health care with professional nursing theories to safeguard and improve the health of populations in the community (CPHA, 2010; CHNC, 2011). To understand public health nursing, it is necessary to know how public health works. The emphasis in **public health** is on the health of the entire population. Historically, government-funded agencies have supported public health programs that improve food and water safety and provide adequate sewage disposal. Public health policy has largely been responsible for the dramatic gain in life expectancy for North Americans during the past century (McKay, 2008; Shah, 2003). The goal of public health is to achieve a healthy environment for everyone. **Public health principles** of disease prevention, health promotion and protection, and healthy public policy (CPHA, 2010) can be applied to individuals, families, groups, or communities. Public health practice calls for competencies (i.e., knowledge, skills, attitudes) that cross the boundaries of specific disciplines and are independent of programs and roles (Public Health Agency of Canada [PHAC], 2007). These competencies include “population health assessment, surveillance, disease and injury prevention, health promotion, and health protection” (PHAC, 2007, p. 1; see also CHNC, 2009).

A public health focus requires understanding the needs of a population. Focus may be narrowed to vulnerable populations (e.g., low-income families, recent immigrants). Public health professionals must understand factors influencing the health promotion and health maintenance of groups, trends and patterns influencing disease or risk occurrence within populations, physical and social environmental factors contributing to health and illness, and political processes used to influence public policy (see Chapter 1, “Determinants of Health”).

The **population health** promotion approach (Hamilton & Bhatti, 1996) provides a framework for thinking about health and taking action to improve the health of populations. Action is directed primarily at community levels. Strategies address the determinants of health in order to improve population health and reduce risks (see Chapter 1). Most health determinants involve other sectors of society such as education, agriculture, business, and government. Multisectoral collaboration between the health sector and other sectors is essential, broadening the scope of nursing practice in the community. Population-based public health programs focus on disease prevention, health protection, and health promotion, which provide a foundation for health care services at all levels (see Chapter 2).

Using public health principles helps public health nurses to understand the environments in which clients live, the factors that influence client health, and the types of interventions supportive of client health. Public health nurses perceive value in their distinctive practice, which enables them to see “the big picture” as a result of their “broad health knowledge base, in depth understanding of the community and community resources, and . . . appreciation of individual– family–community interrelationships” (Reutter & Ford, 1996, p. 8). Figure 4-1 illustrates a framework for public health programs that provides a means of organizing program development in public health practice (Edwards & Moyer, 2000).

Successful public health nursing practice involves empowerment-based strategies initiated by building relationships with the community and being responsive to changes within it (Aston et al., 2009; Baisch, 2009; CPHA, 2010; CHNC, 2011). For example, when increasing numbers of grandparents are caring for their grandchildren in a community, nurses can collaborate with local schools and agencies to create a program that might include an opportunity for peer support and education about available resources. The public health nurse is responsive by being active in the community; knowing its members, needs, and resources; working collaboratively to establish health promotion and disease prevention programs; and advocating for program and public policies that promote health and build capacity to identify and address health issues among individuals, families, communities, and service providers. This means developing and maintaining relationships with other professional systems and individuals and encouraging them to respond to a population’s needs.

Home Health Nursing

Home health nursing, also known as **community-based nursing**, involves acute, chronic, and palliative care of individuals and their families that enhances their capacity for self-care and promotes autonomy in decision making (Ayers et al., 1999; CHNC, 2011). Nursing takes place in community settings such as the home, a long-term care facility, or a clinic. The nurse’s competence is based on critical thinking and decision making at the level of the individual client: assessing health status, selecting nursing interventions, and evaluating care outcomes. Because they provide care where clients live, work, and play, home health nurses need to be individual and family oriented and also need to appreciate the community context (CHNC, 2010).

Components of home health nursing practice include self-care as a client and family responsibility; preventive care; care within the community context; continuity of care between home and health system services; and collaborative client care among health practitioners (CHNC, 2011). Nurses use their clinical expertise to provide direct care (e.g., a case manager monitors clients recovering from stroke and provides rehabilitation services). Nursing supports and improves clients’ quality of life. Illness is seen as one aspect of clients’ everyday lives. Nursing tends to be problem focused, addressing client needs for primary, secondary, and tertiary prevention (CHNC, 2011).

A strong theoretical foundation for home health nursing, and community health nursing broadly, is provided by the human ecological model, which conceptualizes human systems as open and interactive with the environment (Aston et al., 2009; Baisch, 2009; Chalmers et al., 1998). In an ecological model, the individual is viewed within the larger systems of

Figure 4-1 Framework for public health programs. **Source:** From N. Edwards et al. (1995). *Building and sustaining collective health action: A framework for community health practitioners*. Ottawa: Community Health Research Unit, Pub. No. DP95-1, as cited by Edwards, N. C., & Moyer, A. (2000). Community needs and capacity assessment: Critical component of program planning. In M. J. Stewart (Ed.): *Community nursing: Promoting Canadians' health* (2nd ed., p. 433), Toronto: W. B. Saunders.

family, social network, community, and society, which can be depicted as four concentric circles: the innermost circle of the client and the immediate family, the second circle of people and settings that have frequent contact with the client and family, the third circle of the local community and its values and policies, and the outermost circle of larger social systems such as business and government (Ayers et al., 1999). A home health nurse must understand the interaction of all systems while caring for clients and families in the home environment. Nurses typically become involved in the domain of the first three circles. For example, as a home health nurse, you work closely with a client recently diagnosed with diabetes and with the family to establish a care plan. You use observations of the client's lifestyle when considering an exercise schedule and meal routines. Knowing community resources (e.g., shops with glucose monitoring supplies, local diabetes support groups) enables you to provide comprehensive support.

Home health nursing is family-centred care (Ayers et al., 1999; CHNC, 2010). This care requires knowledge of family theory (see Chapter 19), cultural diversity (see Chapter 9), communication (see Chapter 17), and group dynamics. Empowerment-based strategies guide you to work in partnership with clients and families (Toofany, 2007), in planning, decision making, implementation, and evaluation of health care approaches.

The Changing Focus of Community Health Nursing Practice

Community health nursing practice has changed since the 1960s in response to social, economic, and political influences. Changes were documented by Chalmers et al. (1998), who interviewed community health nurse educators, administrators, and staff nurses who worked in public health agencies,

home health services, and community health centres in Manitoba. The nurses noted shifts in practice focus from universal programs to programs directed to high-risk or vulnerable groups, from generalized to specialized practice, and from delivery of traditional public health services to more community-based acute care. These shifts resulted in increasing demands on community health nurses to manage more complex care situations. In 2005, Meagher-Stewart et al. reported the practice challenges articulated by public health nurses and nurse administrators in Nova Scotia (Box 4-3), highlighting conditions that undercut their ability to work directly with clients, a highly valued aspect of their practice. The trends identified by Chalmers et al. remain relevant because they reflect continuing shifts and related challenges in community health nursing practice over a decade after they were publicized.

Although many changes are consistent with the principles of primary health care and health promotion, there is concern that some changes put universal accessibility of public health nursing services at risk (Meagher-Stewart et al., 2005). This concern also emerged in home health practice, in which a policy agenda of increasing medicalization "potentially leads to further marginalization of the most vulnerable" (Duncan & Reutter, 2006, p. 242). Home health care case managers expressed concern about limits on their practice arising from a conflict between professional discourse that guides practice and economic discourses that drive organizational priorities (Ceci, 2006). Underwood et al.'s (2009) examination of enablers to public health nursing practice identifies opportunities to enhance capacity to counter current system pressures. They concluded that "community nurses work well together, but need time, flexible funding and management support to strengthen relationships with their communities and clients and to build partnerships with other professionals" (p. I-10).

► BOX 4-3

Challenges to Community Health Nursing Practice

- Pulled between documenting work and valued practice with clients
- Torn between prescribed programs and community partnership activities
- “Never enough time,” especially for higher needs
- Increased task orientation, specialization, and working in silos
- Lack of evaluation of program effectiveness
- Increasing inequity of programs to rural, seniors, and low-income populations
- Feeling stretched related to shortage of nursing and administrative support staff
- Staying current on health information
- Loss of connection and visibility with the community

Vulnerable Populations

Community health nurses care for clients from diverse cultures and backgrounds and with various health conditions. However, because of changes in the health care delivery system, high-risk groups have become the nurses' principal clients.

Vulnerable populations of clients are those who are likely to develop health problems as a result of excessive risks, who experience barriers when trying to access health care services, or who are dependent on others for care. Vulnerability can be understood in relation to the determinants of health, particularly social determinants that compromise socioeconomic status, literacy, and social inclusion (see Chapter 1). People living in poverty, homeless people, people in precarious circumstances (such as women in abusive interpersonal relationships), people with chronic conditions and disabilities, and people who engage in stigmatizing risk behaviours (including substance abuse and unsafe sexual practices), as well as Aboriginal peoples and new immigrants and refugees, are examples of vulnerable populations (Beiser & Stewart, 2005). Vulnerable individuals and their families often belong to more than one of these groups and may live in communities that can be characterized as vulnerable. Frequently, vulnerable clients come from a variety of cultures, have beliefs and values different from the mainstream culture, face language barriers, and have few sources of social support (Chalmers et al., 1998). Their distinctive needs contribute to the challenges that community nurses face.

To provide competent care to vulnerable populations, nurses in community health care practice must be comfortable with diversity as valuable to individual and social well-being. Culture, ethnicity, ability, economic status, gender, and sexual orientation are all aspects of diversity in Canadian society. Comfort with diversity requires more than tolerance of difference, which implies that the dominant culture is the reference point. Chapter 9 addresses factors influencing individual differences within cultural groups and the nurse's role in providing culturally competent and safe care. To be culturally competent and safe, you must be able to understand clients' cultural beliefs, values, and practices in order to work with them to determine their needs and the interventions most

likely to improve their health. You cannot judge or evaluate a client's beliefs and values about health in terms of your own culture. Communication and caring practices are crucial for understanding clients' perceptions and for planning effective, culturally competent and safe health care. You need to be aware of cultural and ethnic determinants of health, differing beliefs about health and medicine among ethnic communities, and barriers to accessing care that affect members of minority or marginalized populations.

Vulnerable populations typically experience poorer health outcomes than people with ready access to resources and health care services (Beiser & Stewart, 2005; Raphael, 2009). Higher morbidity and mortality rates characterize members of ethnically and racially diverse minority groups (Barr et al., 2002; Hwang, 2000). Members of vulnerable groups frequently experience cumulative risk factors or combinations of risk conditions that make them more sensitive to adverse effects of individual risk factors that others might overcome (Raphael, 2009; Rew et al., 2001). Community health nurses must assess clients from vulnerable populations by considering multiple risk factors and the clients' strengths. Box 4-4 summarizes guidelines for assessing clients from vulnerable population groups.

Poor and Homeless People. People who live in poverty are more likely to live in hazardous environments, work at high-risk jobs, eat less nutritious foods, and experience multiple stressors. They often face practical problems such as limited access to transportation, limited quality child care to support employment, and limited medication or dental coverage from supplementary health benefits. Low-income status is prevalent among lone-parent families, unattached older adults (mostly women), and Aboriginal families (Canadian Population Health Initiative, 2004; Raphael, 2009). Homeless people have even fewer resources than do low-income people. Their vulnerability lies in their social condition, lifestyle, and environment, all of which diminish their ability to maintain or improve their health or access health care. Homeless people live on the streets or in temporary accommodation such as shelters and boarding houses. They may distrust health and social services as bureaucratic and judgemental, using them only when their health has deteriorated (Thibaudeau & Denoncourt, 2000). Chronic health problems worsen because of barriers to supportive self-care and medical care. Homeless people have a high incidence of mental illness and substance abuse. Nurses can help low-income and homeless people identify their capacities and resources, their eligibility for assistance, and interventions to help improve their health (Figure 4-2). For example, Cathy Crowe's work as a street nurse in Toronto includes direct care such as “dressing a wound under a highway overpass” and “treating frostbite” as well as advocacy such as “constantly seeking donations like Gatorade to counter dehydration” and “documenting police-inflicted injuries” (Crowe, 2007, p. 6).

People in Precarious Circumstances. Women are at greater risk for problems related to low income, violence, and the stressors associated with unpaid caregiving. Such risks are further complicated for some by geographically isolated settings that challenge women's resilience in maintaining their health (Leipert & Reutter, 2005). Community health nurses' work is guided by their recognition of the need to listen to, respect, and communicate with women in their communities (Leipert, 1999).

Physical, emotional, and sexual abuse and neglect are major public health problems, particularly affecting older adults,

➤ BOX 4-4

Guidelines for Assessing Members of Vulnerable Population Groups

Setting the Stage

- Create a comfortable, nonthreatening environment.
- Learn as much as you can about the culture of the clients you work with, to understand traditions and values that influence their health care practices.
- Provide culturally competent assessment by understanding the meaning of language and nonverbal behaviour in the client's culture.
- Be aware that the individual or family may have priorities, such as financial or legal problems, that, within your scope as a nurse, you may need to help them deal with before specific health concerns can be addressed.
- Collaborate with others as appropriate; connect your client with someone who can help.

Nursing History of an Individual or a Family

- You may have only one opportunity to work with a vulnerable person or family. Try to document a history that provides essential information you need to help on that day. Organize what you need to ask, and be prepared to explain why the information is necessary.
- Use a modified comprehensive assessment form to focus on the distinctive needs of the vulnerable group. Be flexible. With some clients, it is impractical and unethical to ask all questions on the form.
- Include questions about social support, economic status, resources for health care, current health problems, medication, and how the person or family manages their health. Your goal is to obtain information that will enable you to provide family-centred care, work with strengths, and address concerns.

Physical Examination or Home Assessment

- Complete as thorough a physical examination (on an individual) or home assessment as you can. Collect only information you can use to work with the individual or family.
- Be alert for indications of mental or physical abuse, substance use, or differences from expected physical examination findings.
- Observe a family's living environment. Does the family have running water, functioning plumbing, electricity, and access to a telephone? Is paint peeling on the walls and ceilings? Are room ventilation and temperature adequate? Is the home next to a busy highway, exposing the family to high noise levels and automobile exhaust?

Adapted from Sebastian, J. G. (2006). Vulnerability and vulnerable populations: An overview. In M. Stanhope & J. Lancaster (Eds.), *Foundations of nursing in the community: Community-oriented practice* (pp. 403–417). St Louis, MO: Mosby.

women, and children (CPHA, 1994; Sebastian, 2006). Abuse occurs in many settings, including the home, workplace, school, health care facility, and public areas, and is most often committed by an acquaintance of the victim (CPHA, 1994). When dealing with clients at risk for or who may have suffered abuse, you must provide protection for them. Interviews with clients should occur in private when the individual suspected of being the perpetrator is not present. Clients who have been abused often fear retribution if they discuss their problems with a health care provider. Most regions have reporting agencies or hotlines for notification when an individual has been identified as being at risk, and you can work with clients to

Figure 4-2 Nursing students working in a Care Bus to provide basic health care to the homeless population.

reflect on concerns, identify acceptable alternatives, and make decisions about their situation.

Unintentional injuries, unemployment, depression, and suicide are a concern among youth, particularly young men and those in Aboriginal communities. “Community health nurses who are concerned with adolescent health promotion must consider the broad range of factors that affect adolescent health decisions and behaviours. Individual, family and environmental factors must be considered, together with many structural and societal factors” (Gillis, 2000, p. 257).

A focus on how the physical environment influences health has re-emerged as a priority for community health nurses, reflecting increasing public concerns about potential exposure to hazardous physical environments. These environments include natural and built environments. The quality of the built environment of daily life—dwellings, schools, workplaces, and community spaces—has an impact on individual and community health. Environmental racism, documented in “communities of colour” who experienced disproportionate exposure to hazardous waste facilities, landfills, and incinerators (Cole & Foster, 2001), is a form of environmental injustice, encompassing racial and class-based discrimination that underpins such exposures in marginalized communities. An environmental justice perspective can support action to address inequitable distribution of health-promoting amenities, such as walkable neighbourhoods and park space, and of hazardous exposures, such as unsafe housing, toxic industrial sites, and polluted ground waters (Cutts et al., 2009).

People with Chronic Conditions and Disabilities. “Chronic conditions are impairments in function, development, or disease states that are irreversible or have a cumulative effect” (Ogden Burke et al., 2000, p. 211). There are physical and emotional aspects of living with chronic conditions. Societal trends toward greater family mobility, maternal employment, smaller families, and female-headed, lone-parent, low-income families are challenges for families caring for children with chronic conditions (Ogden Burke et al., 2000). Older adults experience more chronic conditions as they age (Denton & Spencer, 2010). The shift in health care service delivery from institutional to community-based care places demands on families, particularly women, to provide caregiving in the community. You need to work with individuals, families, and

communities to promote adequate support for family caregivers and access to resources and services.

For a client with a severe mental illness, multiple health and socioeconomic problems must be explored. Many such clients are homeless or marginally housed. Others are unable to work or provide self-care. They require medication therapy, counseling, housing, and vocational assistance. No longer hospitalized in long-term psychiatric institutions, clients with mental illness are offered resources within their community. However, many communities face continuing difficulties establishing comprehensive, coordinated, and accessible service networks (Health Canada, 2002; Shah, 2003). Many clients who lack functional skills are left with fewer, more fragmented services.

Collaboration among community resources is key to helping people with mental illness obtain health care. For example, the interdisciplinary Psychiatric Outreach Team of the Royal Ottawa Hospital provides mobile services to shelters and drop-in centres to initiate mental health care, assist in linking clients to community resources, and provide education and assistance in connecting with mental health and addiction treatment (Farrell et al., 2005).

With the increasing population of older adults, there is a corresponding increase in the number of clients with chronic disease and a greater demand for health care (Craig, 2000). You must view health promotion from a broad perspective, by understanding what health means to older adults and ways they can maintain their own health. Among individuals who feel empowered to control their own health, the incidence of disability from chronic disease is lower (Baas et al., 2002). You can help improve the quality of life for older adults.

People Who Engage in Stigmatizing Risk Behaviours. Potentially stigmatizing risk behaviours include substance abuse and unsafe sexual practices. The social determinants of health provide a holistic perspective to address social and structural conditions that influence behaviour and to challenge the “unprecedented reliance on interventions that focus on addressing what is wrong with the individual” (Shoveller & Johnson, 2006, p. 56). Substance abuse is a general term for the use of illegal drugs and the abuse of alcohol and prescribed medications such as anti-anxiety agents and narcotic analgesics. Clients who abuse substances also frequently have health and socioeconomic problems. A substantial proportion of adult HIV and AIDS cases have been attributed to injection drug use (Geduld & Gatali, 2003). Substance abuse, particularly alcohol abuse, remains a serious problem among Canadian adolescents (Gillis, 2000; Health Canada, 2007; Leatherdale & Ahmed, 2010). Socioeconomic problems often result from financial strain, employment loss, and family breakdown. The incidence of unsafe sexual practices and multiple risk-taking behaviours remains high among young people (Smylie et al., 2006). Unsafe sex creates serious health and social risks, including the risks of unplanned pregnancy and acquiring sexually transmitted infections (e.g., HIV infection and AIDS). Unplanned adolescent pregnancy poses risks for both mothers and infants, including pregnancy complications (DiCenso & Van Dover, 2000), low income, low academic achievement, unemployment, violence (Gillis, 2000), and stigma (Fulford & Ford Gilboe, 2004). You can partner with clients to assess the circumstances that contribute to substance use, unsafe sexual practices, and other risk behaviours and identify strategies to address the often multiple and inter-related concerns. For example, Steenbeek (2004) identified strategies such as peer leader training and self-advocacy skill

development within an empowering health promotion framework to prevent sexually transmitted infections among Aboriginal youth. The AIDS Prevention Street Nurse Program (Box 4-5) and the Nursing Story (Box 4-6) illustrate **harm reduction**, an important but controversial approach to health promotion that is based on user input and demand, compassionate pragmatism, and commitment to offer alternatives to reduce risk behaviour consequences, to accept alternatives to abstinence, and to reduce barriers to treatment by providing user-friendly access (Hilton, Thompson, Moore-Dempsey, & Janzen, 2001; Pauly et al., 2007; Shah, 2003).

BOX 4-5 RESEARCH HIGHLIGHT

AIDS Prevention Street Nurse Program

Research Focus

The AIDS Prevention Street Nurse Program in Vancouver provides outreach services for preventing HIV and sexually transmitted infection in vulnerable, high-risk clients (Hilton et al., 2009; Hilton, Thompson, Moore-Dempsey, & Hutchinson, 2000, 2001). The program was awarded the Provincial Health Officer's Award of Excellence in 2007 and acknowledged as symbolizing best nursing practices and organizational commitment. Community health nurses with the program use harm reduction and health promotion approaches in their work. Harm reduction includes needle exchange for injection drug use, education to promote safer drug use and sexual behaviour, and support to clients in addiction treatment programs. Nurses go where the clients are: clinics, drop-in centres, detoxification centres, jails, door-to-door in hotels, or on the street.

Research Abstract

The purpose of the program evaluation study was to describe the nurses' work and its impact on clients, the challenges that nurses faced, and the program fit with other services (Hilton et al., 2001). Program nurses were interviewed, as were clients of the program, including youths living on the streets, sex trade workers, and injection drug users. Challenges facing nurses include building trust with clients, providing needed care or resources, and involving other health care providers. Clients reported gaining knowledge, feeling better about themselves, being supported, and changing their behaviours to help themselves and others (Hilton et al., 2000, 2001).

Evidence-Informed Practice

- Key strategies for reaching vulnerable populations include working with clients “at their location, on their own terms, and according to their own agenda” (Hilton et al., 2001, p. 274) and encouraging and facilitating client participation and choice.
- Client empowerment can be promoted through nurses' nonjudgemental care, trust, and respect.
- Educating marginalized clients about health promotion and harm prevention increases their self-concept and encourages them to change their behaviour.

BOX 4-6 NURSING STORY

Harm Reduction Nursing

Harm reduction initiatives, such as needle exchange programs now available in most Canadian provinces, exemplify community health nursing practice guided by primary health care, health promotion, empowerment, and ethical principles. The leadership, creativity, and dedication of nurses contributed significantly to the development of these initiatives. For example, Wood et al. (2003) successfully advocated for the establishment of a supervised injection site for injection drug users as part of the day program services provided by the Dr. Peter Centre in Vancouver's Downtown Eastside. Collaborating with local HIV and AIDS network members, researchers, and street nurses (see Box 4-4), they developed policies, procedures, and protocols to deliver harm reduction services to a highly vulnerable population in which stigmatizing risk behaviours were compounded by homelessness, precarious life circumstances, and chronic conditions and disabilities. In addition to the supervised injection site, nurses provide sterile drug injection supplies through a needle exchange program, teach about safe sex, offer condoms, talk with sex trade workers about safer ways of dealing with johns, counsel on addiction, support methadone maintenance regimens, and help when individuals are ready to enter detoxification programs or rehabilitation (Griffiths, 2002, p. 12). Serving the same population in Vancouver, Insite, North America's first dedicated legal supervised drug injection facility, opened in 2003 with diverse stakeholder engagement and provides health care, counselling, education, and support from a multidisciplinary team that includes nurses (Small et al., 2006; Wood et al., 2008). Since 1989, nurses with the Streetworks initiative in Edmonton have worked from several fixed daytime sites and from a mobile van for evening outreach to offer harm reduction strategies in partnership with agencies serving the inner-city community. Nurses' work in these initiatives illustrates many of the role dimensions needed for community health practice, including activities as communicator, facilitator, collaborator, coordinator, educator, care or service provider, community developer, policy formulator, and researcher. "Using professional practice to create change, the passion and leadership of a few nurses are resulting in an innovative approach. If such an approach were adopted across Canada, the number of human lives and health care dollars saved would be monumental" (Wood et al., 2003, p. 24). You are encouraged to reflect on these nursing roles and activities by reading more about these and similar programs in communities across the country.

Standards, Competencies, Roles, and Activities in Community Health Nursing

Nurses in community health practice must have a broad base of knowledge and skills in order to work with clients to meet their health care needs and develop community relationships. Primary health care and health promotion approaches help nurses recognize the interplay between individual experience and social conditions, the value of diversity, and the importance of building capacity to promote health-enhancing change. The CHNC (2011) identified seven standards of practice for community health nurses: health promotion; prevention and health protection; health maintenance, restoration, and palliation; professional relationships; capacity building; access and equity;

and professional responsibility and accountability. These standards "define the scope and depth of community nursing practice; establish criteria and expectations for acceptable nursing practice and safe, ethical care; and inspire excellence in and commitment to community nursing practice" in nursing care, education, administration, and research (CHNC, 2011, p. 7). Nurses in community health nursing practice are responsible for meeting these professional nursing standards (CHNC, 2011). In addition, nurses in the specialty practice areas of public health or home health are responsible for meeting relevant competencies (i.e., having required knowledge, skills, and attitudes) (see CHNC, 2009, 2010; PHAC, 2007).

Community health nurses have multiple important roles in health promotion, disease and injury prevention, health protection, health surveillance, population health assessment, and emergency preparedness and response (CPHA, 2010). A summary of key activities engaged in by nurses in meeting responsibilities for these multiple roles was articulated in 1990 and updated in 2010 by the CPHA and is presented in the following sections.

Communication. *Communication* skills support all other activities in community health nursing practice. Skill as an effective communicator is closely related to the leadership and advocacy skills of the facilitator. You may use negotiation and mediation to foster collaboration.

Facilitation. To *facilitate* is to promote. Community health nurses work within a participatory process to identify issues, develop goals for change, and implement strategies for action and evaluation of results. Leadership and advocacy skills are key to these activities.

Leadership. *Leadership* focuses on supporting processes that build capacity among participants, rather than on directing or controlling decision making. To develop proactive approaches to health and environmental issues, you will need to apply knowledge of professional, community, and political issues and processes.

Advocacy. *Advocacy*, underpinned by commitment to equity and social justice, fosters attention and action to address social determinants of health and accessibility of care, especially among vulnerable populations. You may help clients become aware of issues that influence their health, build capacity to speak for themselves, and access resources to address issues.

Consultation. Community health nurses *consult* with clients and also community members, health care providers, professionals from other disciplines, members of other sectors, policymakers, and government officials. You respond to inquiries about and make referrals to community resources. By developing collaborative relationships, you support client access to these resources.

Team Building and Collaboration. *Team building and collaboration* is a way of working together characterized by recognition of interdependence, collective responsibility, and negotiated equity in relationships (Gray, 1989; Labonte, 1993). You may participate in a team or collective process as a collaborator with clients, community members, agencies, and sectors. This process is supported by developing honest relationships and mutual respect, recognizing many forms of expertise, valuing diversity, and being organized and committed.

Building Capacity. *Building individual and collective capacity* is a means to address health issues and overcome barriers to achieve enhanced quality of life outcomes (Labonte et al., 2002). You may help community members understand

their strengths and abilities, develop leadership, extend social networks, and work together. Group process skills are integral to supporting capacity-building activities.

Building Coalitions and Networks. Community health nurses also use capacity-building skills in situations where there is need for *building coalitions and networks* to support collective action on health issues. You may work with community members to identify the type of coalition or network that best fits their intended purpose, to clarify leadership roles, to create links between the coalition or network and the community at large, and to provide requested support to the coalition or network.

Outreach. *Outreach* supports a holistic approach to community nursing practice and is particularly critical when you work with vulnerable populations. Outreach often involves locating services in places that are considered safe or comfortable for potential users, using acceptable approaches to care, and working with clients “where they are at” including using harm reduction strategies.

Resource Management, Planning, Coordination. *Coordination*, often also involving *resource management and planning*, has long been associated with nursing practice. You work with clients and diverse agencies to plan and coordinate activities, resources, access, and care to promote client health. These activities complement activities focused on education, care/counselling, and community development.

Case Management. *Case management* skills are closely linked with resource management, planning, and coordination skills and activities. Your work will commonly involve case finding, including identification of potential clients in vulnerable circumstances, in addition to assessment as a basis for planning, implementing, and evaluating actions to address identified issues. Development of trusting relationships with clients, capacity building, and collaboration are central to effective case management.

Care/Counselling. Community health nurses provide *care/counselling* as they work with clients to promote and protect health and to prevent injury and illness. In many communities, home visiting remains integral to practice, as do services such as health assessment and immunization clinics. You treat illness, monitor risk conditions, educate or guide informed decision making, and support client self-care.

Referral and Follow-Up. Community health nurses work with individuals and families to make decisions about appropriate *referral and follow-up* care, services, or resources. You will need to develop and link with other providers, agencies, and networks to support effective and appropriate referral and follow-up.

Screening. *Screening* is intended to identify emerging, typically presymptomatic health problems for early treatment and improved health outcomes. Screening contributes to timely case finding. You work to ensure that clients understand and consent to screening activities, that acceptable approaches are used to support culturally safe and competent care, and that appropriate referral and follow-up are completed.

Surveillance. *Surveillance* information is used to enhance understanding of health threats or problems, their natural course, and intervention effectiveness. You may be involved in informal surveillance as well as formal or legally mandated protocols that contribute to documenting, interpreting, and sharing relevant surveillance information.

Health Threat Response. Community health nurses may be involved in *health threat response* procedures, such as

when a natural disaster occurs in a community. You must understand and follow established procedures that may include case investigation, provision of preventive care, and referral and follow-up for those needing treatment.

Health Education. Skillful and effective client education with individuals and groups requires a broad knowledge base, as well as communication and learning process skills. Nurses provide information to support community, family, and individual decision making. You may participate in formal education sessions, such as prenatal classes, or in informal sessions, such as discussions with families during home visits.

Community Development. Community health nurses apply knowledge of *community assessment and development* to support community participation. Participation encourages open identification of issues, shared decision making, egalitarian relationships, and collective ownership of action (Labonte, 1993). Participation and empowerment are closely linked.

Policy Development and Implementation. Activities related to *policy development and implementation* include identifying the need for policy and program development; participating in program development, implementation, and evaluation; helping establish policies to support practice; and using political processes to promote health. You need to support the collective voice of professional associations (e.g., CNA, CHNC) to advocate for health enhancing public policy. Falk-Rafael (2005) contends that “nurses, who practice at the intersection of public policy and personal lives, are, therefore, ideally situated and morally obligated to include political advocacy and efforts to influence health public policy in their practice” (p. 212).

Research and Evaluation. *Research and evaluation* are used to generate information, identify issues, determine directions for action, consider strategies to promote change, and assess results. You will need to review research and apply knowledge to practice. You may also engage in research and evaluation projects as a participant or investigator to support evidence-informed decisions about practice.

Community Assessment

As a community health nurse, you need to assess the community, the environment in which people live and work. Without an understanding of that environment, any effort to promote health and to support change is unlikely to succeed, whether you work with an individual, a family, a group, or a community as client.

The community can be seen as having three components: the locale or structure, the social systems, and the people. A complete assessment involves studying each component to understand the health status of the people and the health determinants that influence their health as a basis on which to identify needs for health policy, health program development, and service provision (for detailed descriptions of community assessment strategies, see community health nursing textbooks such as Stamler & Yiu, 2011; Stanhope et al., 2011; and Vollman et al., 2012). To assess the locale or structure, you might travel around the community and observe the physical environment, the location of services, and the places where residents congregate (completing a windshield or walking survey). Information about social systems, such as schools, health care facilities, recreation, transportation, and government, may be acquired by visiting various sites and learning about their services (observing activities, interviewing key

informants). Community statistics from a local library or health department can help assess a population's demographics and health status (reviewing population data). Discussion with community members, including a social and environmental health history (interviewing key informants, holding focus groups), is also helpful to identify priority issues within the community. It is essential to identify community resources and capacities, as well as issues and problems (Edwards & Moyer, 2000).

Recall the determinants of health as you consider the following scenario. As a community health nurse, you wish to familiarize yourself with the local area to help you begin to identify potential health concerns and available resources that will guide your work with the community. Your windshield and walking surveys reveal an older, high-density neighbourhood where pawn shops and bars outnumber grocery stores, schools, and community recreation facilities. You observe a culturally diverse population, including young families and older people who interact with each other at community events sponsored by faith-based groups and social agencies. Your observations are reinforced in discussions as you develop relationships with community leaders and health and social agency staff, whose perspectives are supported by census tract data and regional health statistics. You are alerted to tensions related to high unemployment and language barriers to services. Once you have a good understanding of the community, you may then perform individual or family client assessment against that background. For example, consider assessment of families in a low-income housing complex. Is lighting along walkways and entryways operational? Do they feel comfortable calling on their neighbours for assistance if necessary? Are health and social services easy to reach when needed? Do they feel a sense of belonging in the neighbourhood? No individual or family assessment should occur in isolation from the environment and conditions of the community setting. A collaborative approach to community assessment grounded in an empowerment process helps establish working relationships, identify shared concerns, recognize collective capacities, and develop effective strategies to enhance health.

Promoting Clients' Health

The challenge for nurses in community health practice is how to promote and protect the health of clients, whether within the context of their community or with the community as the focus. You may bring together the resources necessary to improve the continuity of client care. In collaboration with clients, health care and social service providers, and other community members, you coordinate health care services, locate appropriate social services, and develop innovative approaches to address clients' health issues.

Perhaps the key to being an effective community health nurse is the ability to understand clients' everyday lives. The foundation for this understanding is the establishment of strong, caring relationships with clients (see Chapters 17 and 18) that support empowerment as an active process rooted in cultural, religious, and personal belief systems and awareness of links between personal lives, community experiences, and social political contexts (Falk-Rafael, 2001, 2005). The quasi-insider status of nurses in a community often enables them to identify local patterns and needs that can be addressed through programs, policies, and advocacy (Baisch, 2009; SmithBattle et al., 2004) that are responsive, supportive, and effective. The

day-to-day activities of family and community life and the cultural, economic, and political environment influence how you adapt nursing interventions. Once you acquire an understanding of an individual's or family's life, interventions designed to promote health and prevent disease can be introduced. Similarly, understanding the relationships, activities, and concerns of groups and communities is central to health promotion practice. A continuing challenge for community health nurses is to take up their practice in ways that establish meaningful, respectful engagement with people in their communities and that promote individual, family, and collective empowerment, to enhance health in everyday life.

✦ KEY CONCEPTS

- A successful community health nursing practice involves building relationships with the community members and being responsive to changes within the community.
- The principles of public health nursing practice aim at assisting individuals in acquiring a healthy environment in which to live.
- The public health nurse cares for the community as a whole and considers the individual or family to be one member of a population or potential group at risk.
- The home health nurse's competence is based on decision making at the level of the individual client.
- Within an ecological model of home health nursing, the individual is viewed within the larger systems of family, social network, community, and society.
- Vulnerable individuals and their families often belong to more than one vulnerable group.
- The distinctive needs of vulnerable populations contribute to the challenges that nurses face in caring for these clients.
- Exacerbations of chronic health problems are common among homeless people because they have few resources.
- An important principle in dealing with clients at risk for or who may have suffered abuse is protection of the client.
- Clients who engage in risk behaviours such as substance abuse may respond to a harm reduction approach.
- In community health practice, it is important to understand what health means to clients and what they do to maintain their own health.
- A community health nurse must be competent in fulfilling a multidimensional role, including engaging in communication; facilitation; leadership; advocacy; consultation; team building and collaboration; building capacity; building coalitions and networks; outreach; resource management, planning, and coordination; case management; care/counselling; referral and follow-up; screening; surveillance; health threat response; health education; community development; policy development and implementation; and research and evaluation activities.
- Assessment of a community includes assessing population health status and relevant determinants of health in relation to three elements: locale or structure, the social systems, and the people.
- An important consideration in becoming an effective community health nurse is to strive to understand clients' lives.

✦ CRITICAL THINKING EXERCISES

1. You are working with the family of a severely disabled child and learn that no respite services to provide parental support, and only limited educational resources, are available in your community. What activities or roles of the community health

- nurse would be important to establish a special education day care service, operated by volunteer educators?
- Mr. Crowder is a 42-year-old man with diabetes mellitus and visual impairment. Your assessment reveals that he is homeless and spends nights in a local shelter. He is not able to buy medications or ensure adequate diet to control his blood glucose. What factors might you consider to support Mr. Crowder's self-care?
 - Conduct a community assessment of an area that you have visited infrequently. Observe the community locale by driving or walking through the more populated area. Look for the following services: hospital, clinic, pharmacy, grocery store, schools, park or playground, and police and fire departments.

❖ REVIEW QUESTIONS

- The overall goals of a population health approach are to
 - Maintain and improve the population's health and eliminate health disparities
 - Gather information on incidence rates of certain diseases and social problems
 - Assess the health care needs of individuals, families, or communities
 - Develop and implement public health policies and improve access to acute care
- Public health nursing merges knowledge from professional nursing theories and the
 - Population sciences
 - Public health sciences
 - Environmental sciences
 - Social sciences
- Home health nursing involves acute, chronic, and palliative care of clients and families to enhance their capacity for
 - Nursing care that promotes autonomy in decision making
 - Improving their health care and self-care
 - Self-care and autonomy in decision making
 - Learning about their illnesses
- Vulnerable populations are more likely to develop health problems as a result of
 - Acute diseases, homelessness, and poverty
 - Lack of transportation, dependence on others for care, and lack of initiative
 - Poverty, lack of education, and mental illness
 - Excess risks, barriers to health care services, and dependence on others for care
- Which is *not* an aspect of competent care of vulnerable populations?
 - Providing culturally appropriate care
 - Creating a comfortable, nonthreatening environment
 - Assessing living conditions
 - Offering financial or legal advice
- Major public health problems affecting older adults, women, and children are
 - Prescribed medication abuse, poverty, sexual abuse
 - Physical, emotional, and sexual abuse, as well as neglect
 - Acute illnesses, neglect, substance abuse
 - Financial strain, poverty, physical abuse

- A successful community health nursing practice requires
 - A graduate degree in health education or health promotion
 - Building relationships with and responding to changes in the community
 - Taking a passive role to allow the community to initiate change
 - Subspecialty education in public health sciences
- Teaching classes about infant care, cancer screening, and home safety adaptations for older people are examples of a nurse engaging in which activity?
 - Consultation
 - Collaboration
 - Health education
 - Facilitation
- A community health nurse who is directing a client to community resources is an example of which activity?
 - Consultation
 - Collaboration
 - Coordination
 - Research
- A community includes the following three elements, each of which must be assessed:
 - Locale or structure, social systems, and people
 - People, neighbourhoods, and social systems
 - Health care systems, geographic boundaries, and people
 - Environment, families, and social systems

Theoretical Foundations of Nursing Practice

Written by Sally Thorne, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Describe selected theories of nursing practice and differentiate between them.
- Describe challenges inherent in theorizing about nursing practice.
- Recognize selected conceptual frameworks associated with nursing practice.
- Appreciate the historical development of thought related to nursing practice.
- Interpret current debates surrounding various theories of nursing practice.
- Describe relationships between theorizing and other forms of nursing knowledge.
- Appreciate the role of “theorizing” about the essence of nursing.

Although many nursing tasks can be mastered by anyone trained to perform them, the hallmark of nursing practice is a unique body of knowledge combined with a set of principles that guide the systematic application of that knowledge in an expanding array of contexts. **Nursing theory** aims to organize knowledge about nursing to enable nurses to use it in a professional and accountable manner (Beckstrand, 1978).

A **theory** is a purposeful set of **assumptions** or **propositions** that identify the relationships between **concepts**. Theories are useful because they provide a systematic view for explaining, predicting, and prescribing phenomena. Although nursing theories are not generally propositional, they reflect a **conceptualization** of nursing for the purpose of describing, explaining, predicting, or prescribing care (Meleis, 2007). Theories constitute one aspect of disciplinary knowledge and create vital linkages to how inquiry is approached (Fawcett et al., 2001). Nursing theories provide nurses with a perspective from which to view client situations, a way to organize data, and a method of analyzing and interpreting information to bring about coherent and informed nursing practice.

Early Nursing Practice and the Emergence of Theory

Although nursing practices have been documented throughout history (Yura & Walsh, 1973), the advent of modern nursing practice, in which the knowledge and practice of nursing are formalized into a professional context, is often attributed to the work of Florence Nightingale, a visionary leader in Victorian England who created systems for nursing education and practice (see Chapter 3). Contemporary scholars now consider Nightingale's work as an early theoretical and conceptual **model for nursing**. Her descriptive theory provided nurses with a way to think about nursing practice in a frame of reference that focuses on patients and the environment.

Since Nightingale's era, the status of nursing practice has paralleled that of the authority of women in society. After World War II, major developments in science and technology had a powerful influence on health care, including nursing practice. **Nursing science** came into its own. No longer simply applying the knowledge of other disciplines, nurses now began to acquire a unique body of knowledge about the practice of nursing.

Since the 1960s, scientific knowledge has proliferated across all disciplines. In particular, knowledge about nursing has drawn from and contributed to developments in health sciences, basic physical sciences, social and bio-behavioural sciences, social theory, ethical theory, and the **philosophy of science**. Each of these sources has relevance for the interpretation of nursing care and the synthesis of relevant facts and theories for application to practice.

A number of major developments in nursing theory occurred in the late 1960s (Meleis, 2007). The health care system was expanding and changing, influenced by scientific discoveries and technological applications. Disease intervention became more sophisticated and scientifically driven. The focus of society shifted from simply attending to sick and injured people toward the larger problem of curing and eradicating disease, which expanded the influence of physicians over the structure of health care delivery. For the first time, nurses realized the urgency of articulating exactly how their role differed from those of the other health care professionals (Chinn & Kramer, 2011; Engebretson, 1997; Fawcett, 2004; Newman, 1972).

The drive for early theorizing about the practice of nursing was led by nurse educators, who noted that traditional ways of preparing professional nurses were rapidly becoming outdated. Until the 1960s, a nursing apprenticeship model, augmented by lectures offered by physicians, had seemed sufficient. Around this time, nursing educational leaders became inspired to theorize about nursing in order to structure and define what a curriculum oriented to nursing knowledge might contain (Dean, 1995; Orem & Parker, 1964; Torres, 1974). This meant grappling with large theoretical and philosophical questions, such as the following:

- What are the focus and scope of nursing?
- How is nursing unique and different from other health care professions?
- What should be the appropriate disciplinary knowledge for professional nursing practice?

To answer these questions, early theorists developed **conceptual frameworks**, in which they organized core nursing concepts and proposed relationships among these concepts. These conceptual frameworks were "mental maps" whose

purpose was to make sense of the information and decisional processes that nurses needed to apply knowledge to nursing practice (Ellis, 1968; Johnson, 1974; McKay, 1969; Wald & Leonard, 1964). Expressing knowledge about nursing in scientific language created a context in which nursing science gained stature and flourished (Cull-Wilby & Peppin, 1987; Jones, 1997). However, these nursing theories were not the kind of scientific theories that could be confirmed or disproved with empirical evidence (Levine, 1995); rather, they represented ideas about how nurses might organize knowledge, as well as the processes by which they would apply that knowledge to unique practice situations. Table 5-1 defines some of the basic terms that are used in theorizing about scientific issues.

Nursing Process

Early nursing theorists sought to organize the knowledge about the practice of nursing that nurses draw upon to direct their approach to clinical encounters. However, theorists generally lacked ways of systematically explaining how nurses work with knowledge in new situations (Field, 1987). An important early step in the application of knowledge to nursing practice was Orlando's (1961) development of a problem-solving approach that came to be known as the **nursing process** (Yura & Walsh, 1973). This process originally involved four steps: assessment, planning, intervention, and evaluation, whereby each step represented a distinct way in which general nursing knowledge could be applied to unique and individual nurse-patient situations (Carnevali & Thomas, 1993; Henderson, 1966; Meleis, 2007; Torres, 1986):

- **Assessment phase:** Nurses would gather information, including biological, sociocultural, environmental, spiritual, and psychological data, to create an understanding of the patient's unique health or illness experience. Organizing the data would enable the nurses to interpret major issues and concerns (Barnum, 1998) and produce a **nursing diagnosis**: the nurse's perspective on the appropriate focus for the patient (Durand & Prince, 1966).
- **Planning phase:** Nurses would prioritize the issues raised during assessment in relation to the nursing diagnoses, identify which issues could be supported or assisted by nursing intervention, and create a plan of care.
- **Intervention phase:** The plan of care would be carried out.
- **Evaluation phases:** The plan's success or failure would be judged both against the plan itself and against the patient's overall health status; that is, it would be determined whether the intended outcomes had been achieved or whether the nursing intervention strategies required revision. The nursing process was intended as a sequence within which thoughtful interpretation always preceded action, and the effects of action were always evaluated in relation to the original situation.

The nursing process was widely accepted by nurses because it was a logical way to describe basic problem-solving processes in which knowledge was used effectively to guide nursing decisions (Henderson, 1982). Nurses quickly adopted the nursing process because it represented a continuous, rapid cycling of information through each of the phases. Although it was useful for organizing and applying knowledge to clinical practice (Meleis, 2007), some later theorists began to challenge the nursing process as being too linear and rigid for nursing's purposes (Varcoe, 1996).

► **TABLE 5-1** The Terminology of Scientific Theorizing

Term	Description	Example
Concept	A mental formulation of objects or events, representing the basic way in which ideas are organized and communicated.	Anxiety
Conceptualization	The process of formulating concepts.	Framing behavioural patterns as anxiety related
Operational definition	A description of concepts, articulated in such a way that they can be applied to decision making in practice. It links concepts with other concepts and with theories, and it often includes the essential properties and distinguishing features of a concept.	Differentiation and measurement of state and trait anxiety
Theory	A purposeful set of assumptions or propositions about concepts; shows relationships between concepts and thereby provides a systematic view of phenomena so that they may be explained predicted, or prescribed.	Social determinants of illness
Assumption	A description of concepts or connection of two concepts that are accepted as factual or true; includes “taken for granted” ideas about the nature and purpose of concepts, as well as the structure of theory.	“Nursing exists to serve a social mandate”
Proposition	A declarative assertion.	“Clients who receive appropriate nursing care have better health outcomes”
Phenomenon	An aspect of reality that can be consciously sensed or experienced (Meleis, 2007); nursing concepts and theories represent the theoretical approach to making sense of aspects of reality of concern to nursing.	Pain
Theoretical model	Mental representation of how things work. For example, an architect’s plan for a house is not the house itself but rather the set of information necessary to understand how all of the building elements will be brought together to create that particular house.	Biopsychosocial model of health
Conceptual framework	The theoretical structure that links concepts together for a specific purpose. When its purpose is to show how something works, it can also be described as a theoretical model. Nursing conceptual frameworks link major nursing concepts and phenomena to direct nursing decisions (e.g., what to assess, how to make sense of data, what to plan, how to enact a plan, and how to evaluate whether the plan has had the intended outcome). Conceptual frameworks are also often referred to as nursing models or nursing theories (Meleis, 2007).	Orem’s (1971) self-care model for nursing

In current practice, terms such as *clinical judgement* are used to refer to reasoning processes that rely on *critical thinking* and multiple ways of knowing; clinical judgement implies the systematic use of the nursing process to invoke the complex intuitive and conscious thinking strategies that are part of all clinical decision making in nursing (Alfaro-LeFevre, 2008; Benner & Tanner, 1987; Tanner, 1993).

Conceptual Frameworks

The conceptual framework builders of the late 1960s and after are usually referred to as the nursing theorists. All were fascinated with how effective nurses systematically organize general knowledge about nursing in order to understand an individual patient’s situation and determine which of many available strategies would work best to restore health and ameliorate or prevent disease (Orem & Parker, 1964). This reasoning process was different from linear, cause-and-effect reasoning, and it was what the nursing theorists understood to be the hallmark of excellence in nursing practice (Barnum, 1998; Meleis, 2007). Indeed, when effective nurses made intelligent clinical decisions, it was often difficult to determine the

precise dynamics that explained how those nurses applied that knowledge (Benner et al., 1996).

The building of nursing models was an attempt to theorize how all nurses might be taught to organize and synthesize knowledge about nursing so that they would develop advanced clinical reasoning skills (Raudonis & Acton, 1997). Theorists who developed these frameworks and models sought to depict theoretical structures that would enable a nurse to grasp all aspects of a clinical situation within the larger context of available options for nursing care. Table 5-2 describes four types of theory: **grand theory**, **middle-range theory**, **descriptive theory**, and **prescriptive theory**.

Metaparadigm Concepts

Each conceptual framework was an attempt to define nursing by creating a theoretical definition for the substance and structure for determining the key bodies of knowledge that would be needed to understand particular clinical situations (Figure 5-1). This collective body of knowledge was called the **metaparadigm concepts** and included the concepts of person, environment, health care, and nursing care (Fawcett, 1992).

► TABLE 5-2 Types of Theory

Type of Theory	Description
Grand theory	Global, conceptual framework that provides insight into abstract phenomena, such as human behaviour or nursing science. Grand theories are broad in scope and therefore require further application through research before the ideas they contain can be fully tested (Chinn & Kramer, 2011). They are intended not to provide guidance for specific nursing interventions but rather to provide the structural framework for broad, abstract ideas about nursing. They are sometimes called paradigms because they represent distinct world views about those phenomena and provide the structural framework within which narrower-range theories can be developed and tested.
Middle-range theory	Encompasses a more limited scope and is less abstract. Middle-range theories address specific phenomena or concepts and reflect practice (administration, clinical, or teaching). The phenomena or concepts tend to cross different nursing fields and reflect a variety of nursing care situations.
Descriptive theory	Describes phenomena (e.g., responding to illness through patterns of coping), speculates on why phenomena occur, and describes the consequences of phenomena. Descriptive theories have the ability to explain, relate, and in some situations predict phenomena of concern to nursing (Meleis, 2007). Descriptive nursing theories are designed not to direct specific nursing activities but rather to help explain client assessments and possibly guide future nursing research.
Prescriptive theory	Addresses nursing interventions and helps predict the consequences of a specific intervention. A prescriptive nursing theory should designate the prescription (i.e., nursing interventions), the conditions under which the prescription should occur, and the consequences (Meleis, 2007). Prescriptive theories are action oriented, which tests the validity and predictability of a nursing intervention. These theories guide nursing research to develop and test specific nursing interventions (Fawcett, 2004).

Figure 5-1 Nursing's metaparadigm concepts.

Client and Person

By the 1960s, professional leaders recognized that nurses did much more than simply care for hospitalized patients. Because of this, nursing theorists started to use the term *client*, rather than *patient*, to refer to the person at the centre of any nursing process. The term signified a range of health states, including both sickness and wellness, and an explicitly interactive relationship between the nurse and the persons to whom care was directed. At the same time, nurses were becoming aware of their potential to deliver care beyond the individual—that is, to families, groups, and communities. Although theories to articulate the role of nursing care in families and communities also began to arise around this time, most early conceptual models focused on the individual.

To help nurses systematically organize and make sense of the vast amount of information that might be relevant to the care of any particular client, most early models clearly defined the concept of the person. Theorists variously understood a person as a system of interacting parts, a system of competing human needs, or an entity with biological, psychological, social, and spiritual dimensions. Each framework drew attention to multiple aspects of human experience so that the nurse could understand each instance of wellness and illness for its uniqueness within the context of that individual's body, feelings, and situation. Each model depicted a way of thinking about a whole individual, with the aim of helping nurses understand how the implications of any action or intervention could be systematically individualized toward the benefit of all facets of that individual.

Environment

Each conceptual framework reflected an understanding that the person is part of and interacts with a complex environmental system. This environment may involve the person's family and social ties, the community, the health care system, as well as the geopolitical issues that affect health. The early conceptual frameworks helped shape nurses' increasing appreciation of how to work within a larger context of every experience of wellness and illness. In so doing, these frameworks led to a future in which nurses would spearhead advances in social and health care policy, health promotion, and community development.

Health

Because nursing exists within a social mandate to improve the health of both the individual and society, the early theorists

struggled to articulate the overarching goal that drives nursing practice. They defined health as much more than simply the absence of disease or injury but rather as an ideal state of optimal health or total well-being toward which all individuals could strive (see Chapter 1). This definition reflected a vision of nursing care that was relevant to both the individual and society, and applied to all clients, sick or well. It recognized that persons with chronic disease could strive for better health and that overall health could be compromised by psychosocial or spiritual challenges, even among the most physically fit individuals. Although perfect health was not necessarily achievable, this broad conceptualization guided nurses to help all clients reach outcomes that were productive and satisfying.

Nursing

Each early conceptual framework included a unique definition of nursing that linked a view of the client with an understanding of the person's environment, life, and health goals. Built on a distinct subset of knowledge, each conceptual framework presented a coherent and complete belief system about nursing practice, although each did so in different terms and with a different alignment of ideas. Because most nursing scholars of the era assumed that one model would eventually become dominant (Meleis, 2007), competition among the frameworks occurred. Over time, as enthusiasm for the idea of implementing theory-based practice grew, the application of the frameworks in practice became rigid and codified. Although the original focus had been on guiding nurses to think systematically, the implementation process caused the emphasis to shift toward such aspects as using language in particular ways and filling out assessment forms correctly. Many experienced nurses began to conclude that these frameworks actually inhibited their systematic thinking, and much debate ensued with regard to the utility of the models.

Philosophy of Nursing Science

When nursing theorists began developing their frameworks and models, nurses understood the process of building a knowledge base as a matter of science and discovery. In that context, theories were considered logical propositions that could be rigorously tested for their capacity to answer (or not answer) the hypothetical questions posed by a discipline. However, while creating frameworks for the complex reasoning in nursing practice, these early theorists were applying traditional scientific ways of understanding how knowledge works without fully appreciating the limitations of science, especially in relation to complex problems. As thinkers in all disciplines began to move beyond their traditional boundaries, other possibilities for the development of knowledge about the practice of nursing began to emerge.

Scientific Revolutions

Thomas S. Kuhn, a philosopher of science, created a way of thinking about science and knowledge that expanded thought in many disciplines. First published in 1962, his book *The Structure of Scientific Revolutions* was popularized in the 1970s and 1980s as scholars began to realize the potential of its ideas to support new thinking about how knowledge is built. Kuhn challenged the traditional notion of science as a logical progression of discoveries, arguing that major scientific developments occurred only when scientists thought about problems

in radically new ways. These ways of thinking departed from the traditional to such an extent that an entirely different world view, or "paradigm shift," developed. According to Kuhn, scientific advances happen when people think creatively and look beyond established norms. Such creative thinking could stimulate new understandings of problems that were once considered irresolvable (e.g., quantum physics introduced the idea that the behaviour of very small particles could explain atomic behaviour in ways that defied explanation through conventional Newtonian physics). This new way of thinking about the philosophy of science led nurses to consider their theoretical frameworks as not only theoretical propositions about logical relationships among concepts, but as actual world views, or **paradigms**, that might help them grasp the complexities of nursing (Fry, 1995).

Complexity Science

A second major shift in scientific thinking occurred with the introduction of chaos theory (Gleick, 1987). Originating from observations in physics that predictable patterns existed among factors that could not be predicted scientifically, this theory created a new way of approaching complex situations. In rejecting the simple cause-and-effect relationships used in traditional science, chaos theory led to what has been termed *complexity science*. In this kind of science, dynamic and interactive phenomena are reduced to the smallest properties that can be observed within their natural context so that their interactions can be interpreted with as little interference as possible from prior assumptions. For example, chaos theory explains how, in sensitive weather systems, minor variations in initial conditions (e.g., barometric pressure) might explain large-scale physical patterns over time (e.g., hurricanes). These ideas created a new language to apply to scientific thinking. Because experiences of health and illness are exceedingly difficult to understand out of their individual context, chaos theory offered a new way to approach nursing science (Coppa, 1993; Ray, 1998).

Ways of Knowing in Nursing Practice

As ideas shifted, nursing theorists also realized that science was just one of several forms of knowledge necessary for their practice discipline. In 1978, Carper published an influential paper in which she used the expression **ways of knowing** to refer to patterns of knowledge application in nursing practice. Carper articulated a critical role in nursing practice not only for empirical science but also for ethical, personal, and aesthetic knowledge (see Chapter 6). Later theorists added sociopolitical knowledge (White, 1995) and critical thinking (see Chapter 11) to the list of central ways of knowing that are essential to the highest quality of clinical nursing. These ideas contributed to discussions emerging in other social and life sciences around *how* nurses know what they know (Chinn & Kramer, 2011; Kikuchi & Simmons, 1999).

Paradigm Debates Within Nursing

With the new philosophical approach to scientific knowledge, nurses struggled with how to define their work as both an art and a science and as both applied and practical (Donaldson, 1995; Johnson, 1991; Rodgers, 1991; Sarter, 1990). Ideas about the theoretical foundations of nursing practice shifted. Some scholars began to question conceptual models as a valid form

of theorizing (Holden, 1990). The frustration resulting from overly formal and rigid approaches to applying many of these models led to a period of what has been called *model bashing* (Engebretson, 1997). However, the question confronting the early theorists remained as follows: How does a nurse organize and make sense of all available knowledge and apply it intelligently to the challenges that arise in an individual clinical case?

In this context, many nurse scholars began to recognize that the original theories were better understood as philosophical statements than scientific prescriptions. However, one group of theorists, considering some of the original theories to be overly simplistic and insufficiently holistic, began to categorize various nursing models as reflective of two entirely different paradigms of thinking (Parse, 1987). Considering the majority of nursing models and frameworks to be old-fashioned and outdated, this group of theorists coined the term *totality paradigm frameworks* to describe them, contending that this kind of model reduced an understanding of the human person to fragmented parts out of context. They further proposed the term *simultaneity paradigm frameworks* to depict a set of conceptual frameworks they considered to be radically different and preferable by virtue of being both holistic and philosophically sophisticated (Parse, 1987). Some advocates of simultaneity theories continue to depict the diverse universe of theorizing about nursing as reflecting these two mutually exclusive groupings, positioning one set of conceptual frameworks as philosophically and morally superior to what they understand the other to represent (Cody, 1995; Nagle & Mitchell, 1991; Newman, 1992).

Nursing Diagnosis

Another discussion about nursing theory centred on nursing diagnosis. The scholars who devised conceptual frameworks focused on models to assess and interpret data about individual patient situations. However, the conceptual frameworks were less explicit about how to plan, implement, and evaluate nursing care. To fill this gap, nursing diagnosis emerged as an additional phase in that process. In making explicit the idea that nurses arrived at a clinical judgement relating to actual or potential health processes, it became a discrete focus of theorizing about nursing care.

In the 1970s, some scholars noted a need for precise language to categorize and document nursing diagnoses into a taxonomy (Warren & Hoskins, 1990). This resulted in the formation of the North American Nursing Diagnoses Association (NANDA) (see Chapter 13), which held a series of consensus conferences to establish a list of the common patient problems addressed by practising nurses. The nursing diagnosis movement led to considerable general debate on the merits of using NANDA's fixed list of nursing diagnoses as compared to the theoretically infinite options for nursing care that had been intended by the conceptual models (Fitzpatrick, 1990; Roy, 1982). Although it is recognized as practical rather than theoretical (Fitzpatrick, 1990), NANDA's list has become a popular device for organizing nursing care in part because it enables efficient categorization into electronic databases and the subsequent standardization of nursing care plans (Warren & Hoskins, 1990). However, despite its popularity with health care administrators, NANDA's list is recognized by many nurses as a system that relies entirely upon an agreement about what constitutes average wellness and illness experiences. It

can therefore create worrisome barriers to the individualized care of patients (Lee et al., 2006).

Reflections on Conceptualizing Nursing

The scientific and philosophical aspects of today's nursing practice are built on the foundation of early theorizing about nursing. The history of "nursing theory" is the story of an enlightened attempt to articulate excellent clinical reasoning in nursing care. How effective nurses actually use knowledge within the complexity of their clinical reasoning is, however, still difficult to determine. In this context, theorizing about nursing is perhaps best understood as an extended philosophical struggle to make sense of how highly skilled nurses actually think. Instead of arguing the advantages of one nursing theory over another, nursing scholars of today appreciate the creativity of their predecessors within the constrained conceptual contexts in which they were expected to operate.

Major Theoretical Models

Some of the major theoretical models are summarized briefly in Box 5-1; the similarities and differences among them are illustrated. Note, however, that because many nursing theorists based their models on complex combinations of theories from many disciplines, the categorization used here is somewhat oversimplistic. It may be helpful to view the conceptual frameworks in terms of larger theories upon which they have drawn, such as adaptation theory, systems theory, or human needs theory.

► BOX 5-1

Milestones in the Development of Nursing Theory

1859	Florence Nightingale's <i>Notes on Nursing: What It Is and What It Is Not</i> was published (updated version published 1946)
1952	<i>Nursing Research</i> (the first peer-reviewed scientific journal about nursing care) was established
1952	Hildegard Peplau's text on <i>Interpersonal Relations in Nursing</i> was published
1955	Virginia Henderson's definition of nursing was first published in the 5th edition of Harmer and Henderson's (1955) basic nursing text
1961	Ida Orlando introduced the nursing process
1970	Martha Rogers's model was first published
1970	Callista Roy's model was first published
1971	Dorothea Orem's model was first published
1976	The North American Nursing Diagnosis Association (NANDA) list of nursing diagnoses was first published
1976	The University of British Columbia model of nursing practice was first published (Campbell et al., 1976)
1978	Barbara Carper's paper on fundamental patterns of knowing in nursing practice was published
1979	Evelyn Adam's model was first published (English version published 1980)
1981	Rosemarie Parse's model was first published
1987	The McGill model of nursing was first published (Gottlieb & Rowat, 1987)

Practice-Based Theories

All conceptual models of nursing are designed to guide and shape practice. Although their theoretical inspiration is derived directly from the practice setting, many conceptual models do not capture all of what might be influencing that practice, such as societal and demographic changes, current health care belief models, and therapeutic strategies, as well as the political struggles inherent in health care delivery. The early practice theories, therefore, reflect the issues that were shaping the role and context of nursing during those specific time frames.

Florence Nightingale. Whereas most later theorists drew on social and psychological theories, Nightingale was directly inspired by nursing practice. Writing *Notes on Nursing* in 1859, she described conditions necessary to promote health and healing. Her observations during the Crimean War led to the first set of principles for nursing practice, acknowledging the particular importance of the environment, including clean living areas, fresh air, and the presence of light. The role of nursing care included ensuring that wounded soldiers were warm, comfortable, and adequately fed. Torres (1986) noted that Nightingale demonstrated how to think about patients and their environment. By shifting the focus from disease processes toward an environment conducive to healing, Nightingale's conceptualization clearly differentiated the role of nursing from that of medicine.

The McGill Model. Dr. Moyra Allen (Box 5-2) conceived the McGill model, and she and her colleagues developed it (Gottlieb & Rowat, 1987). Systematically studying actual nursing situations, Allen and her colleagues created a way of thinking about nursing that focused on promoting health. They recognized that many patients' health concerns were best approached through changes in lifestyle. The McGill scholars focused on the individual in the context of the family and, like Nightingale, viewed nursing as complementary to medicine. The main features of the McGill model were "a focus on health rather than illness and treatment, on all family members rather than the patient alone, on family goals rather than on the nurse's, and on family strengths rather than their deficits" (Gottlieb & Feeley, 1999, p. 194). Over time, the model has been further developed to demonstrate its application within a range of clinical contexts and settings (e.g., Feeley & Gerez-Lirette, 1992; Feeley & Gottlieb, 1998).

Needs Theories

Many early theorists organized their thinking by conceptualizing the patient as representing a collection of needs. This reflected a common orientation to studying the nature of people, popularized in the 1960s, in which needs, drives, and competencies were thought to hold potential for explaining human behaviour. Of these theories, Maslow's (1954) hierarchy of needs was one of the best known and most influential. The idea that complex human behaviour can be best explained as a response to the competing demands of various basic needs is featured prominently in many nursing models.

Virginia Henderson. Henderson (Harmer & Henderson, 1955) conceptualized the patient as a compilation of 14 basic human needs: to breathe, eat and drink, eliminate waste products, move and maintain posture, rest and sleep, dress and undress, maintain body temperature, be clean, avoid danger, communicate, worship, work, play, and learn. Viewing the patient in this way clearly defined the nurse's role. Accordingly, Henderson defined nursing practice as assisting the individual, sick or well, in the performance of activities that

> BOX 5-2

Milestones in Canadian Nursing History

Moyra Allen, 1921-1996

A creative and independent thinker, Moyra Allen was one of the first Canadian nurses to earn a doctoral degree. She lobbied for collective bargaining rights for nurses and was the founding president of the United Nurses of Montreal. She was also the founder of *Nursing Papers*, later renamed the *Canadian Journal of Nursing Research*.

Allen was a founding member of the World Health Organization committee that developed the criteria for accreditation of nursing schools. She designed an evaluation model for nursing schools and evaluated schools in South America, India, and Ghana. She joined the faculty of the School of Nursing at McGill in 1954 and became professor emeritus in 1985 on her retirement.

In demonstrating her model of nursing, now known as the McGill model, Dr. Allen established The Health Workshop in 1977, a community health facility, in which she put into practice a developmental concept of health and nursing as a prototype of primary health care. The workshop, viewed as complementary to existing services, was staffed with nurses, a community development officer, and a health librarian. The workshop's purpose was to demonstrate the validity of a local health resource managed by nurses that focused on long-term family health. It proved to be an innovative means of improving the health status of families coping with illness and other problems.

Allen received numerous awards, including the Jeanne Mance Award, which recognizes major contributions to the health of Canadians. In 1986, she was named an Officer of the Order of Canada for her outstanding contributions to Canadian nursing.

contribute to health, recovery, or a peaceful death. Henderson's model has remained popular in practice because its language is familiar and easily comprehensible and because it explains how a person's biological, psychological, social, and spiritual components combine to influence the way illness is experienced and health can be regained.

Dorothea Orem. Orem's (1971) self-care theory, the origins of which lay in Henderson's work, was used widely in both nursing practice and research. Orem's theory addressed the ways in which people are responsible for meeting the following universal self-care requisites:

- Maintaining sufficient intake of air, water, and food
- Maintaining a balance between activity and rest, and between solitude and interaction
- Providing for elimination processes
- Preventing hazards to life, functioning, and well-being
- Promoting functioning and growth in social groups in accordance with human potential

Drawing on both human need and developmental theory, Orem's theory focused on the individual's role in maintaining health. This theory emerged at a time when the passive role of the patient was being questioned and the health care system was beginning to shift away from full responsibility for people's health. With increased understanding of illness patterns, Orem acknowledged the effects of multiple lifestyle factors

such as smoking, diet, and exercise, reminding nurses that patients can look after their own health and that they must learn to care for themselves within their families and communities. Thus, the role of the nurse, according to Orem, was to act temporarily for the patient until the patient could resume a more independent role in self-care.

Interactionist Theories

Interactionist theories focused on the relationships between nurses and their clients. These theories defined more clearly the specific human communicative and behavioural patterns by which practitioners met their patients' needs. As the theorists reframed definitions of the nursing profession, they drew from the work of psychologists and psychoanalysts such as Harry Stack Sullivan, Abraham Maslow, and Sigmund Freud.

Hildegard Peplau. Peplau, a psychiatric specialist, defined the core of nursing care as the interpersonal relationship between the nurse and the patient. Building upon the ideas of psychoanalyst Harry Stack Sullivan, Peplau depicted the practice of nursing as an interactive and therapeutic relationship. Peplau felt that such relationships allowed nurses to challenge the practice of long-term stays in large inpatient psychiatric hospitals and to envision supporting patients to achieve independent living. "The kind of person each nurse becomes makes a substantial difference in what each patient will learn as he is nursed through his experience with illness" (Peplau, 1952, p. vii). According to Peplau, a nurse was "an investigator, prober, interpreter, and reporter, using the rich data she extracts from the patient concerning his life. She develops insights, his and hers, into the meaning of a patient's behaviour and helps the patient recognize and change patterns that obstruct achievement of his goals" (Barnum, 1994, p. 217). An early advocate of an orderly and systematic approach to care, Peplau created a way of thinking about nursing care that directed nurses toward preventing illness and maintaining health.

Joyce Travelbee. Writing in the late 1960s and early 1970s, Travelbee also viewed nursing care as an interpersonal process. In contrast to Peplau's more psychoanalytic orientation, Travelbee drew on a school of thought known as *existential philosophy* to guide her theorizing. Travelbee (1971) viewed the "client" as including not only the individual but also the individual's family and community, and she articulated the role of the nurse as assisting clients to "prevent or cope with the experience of illness and suffering and, if necessary, to find meaning in these experiences" (p. 7). Travelbee emphasized that nurses must recognize the humanity of their clients, suggesting that even the term *patient* should be regarded as a stereotypical categorization. Recognizing the reciprocity of human interaction, Travelbee focused attention on the communication that occurs between nurses and their clients as an important vehicle for finding meaning in illness.

Evelyn Adam. Influenced by Dorothy Johnson, as well as by earlier interactionist theorists (George, 1995), Canadian theorist Evelyn Adam (1979, 1980) articulated the essence of nursing as a helping process. From her perspective, the nurse played a complementary-supplementary role in supporting the patient's strength, knowledge, and will. Adam's model drew on Henderson's framework of basic human needs and extended it into a model that would explain not only how nurses conceptualized the patient but also how they applied that knowledge in the context of a helping relationship characterized by empathy, caring, and mutual respect.

Systems Theories

In the 1970s and 1980s, as conceptual models of nursing became more sophisticated and structured, several theorists drew on general systems theory (von Bertalanffy, 1968) for guidance in conceptualizing the complexity of human health. The main appeal of systems theory was that it accounted for the whole of an entity (the system) and its component parts (subsystems), as well as the complex interactions between the parts and the whole. In this way, systems theory allowed theorists to expand the conceptualization of nursing practice through both structure and process, whereby the individual was viewed as an open system in constant interaction with his or her environment. Being outside the system, the nurse became one of the many forces to have an effect on that system. Using this perspective, nurses were encouraged to appreciate the interactions of a system with its component parts and with its environment. Systems approaches helped nurses recognize that intervention in any one part of a system would produce consequent reactions in other parts, as well as in the system as a whole. Regardless of how each theorist depicted the nature of the system, these general principles common to all living systems were featured in each of the nursing systems models.

Dorothy Johnson. Johnson's theoretical work was popularized in the early 1960s through distribution of her class notes and speeches, but it remained unpublished until much later (Grubbs, 1980; Johnson, 1980). In her nursing model, Johnson identified the individual as a behavioural system with seven subsystems, each of which has a goal, a set of behaviours, and a choice. The notion of goals of the subsystems was based on the drives that were considered universal and applicable to all patients. However, the meanings attributed to each goal and the set of behaviours for achieving goals were seen as highly individual and unique to each patient. Together with the choices made by the patient in relation to meeting his or her behavioural system goals, each subsystem also had a function that could be considered analogous to the physiological function of a biological system (Meleis, 2007).

The University of British Columbia Model. The behavioural systems model developed at the University of British Columbia (UBC) School of Nursing was inspired by Johnson's model and developed by a committee led by Margaret Campbell that included several of Johnson's former students. Broadening the view of human experience on the basis of behavioural drives, the UBC model depicted the behavioural system as being composed of nine basic human needs, each of which is shaped by the psychological and socio-cultural environment within which it is expressed (Campbell et al., 1976). Whereas needs were considered universal and therefore fundamental to human experience, the specific goals toward which needs-related human behaviour were directed and the strategies for achieving those goals were recognized as unique to individuals and their particular physiological, psychological, or social circumstances (Thorne et al., 1993). Thus, the UBC model provided a structure by which general knowledge about human health and illness could be combined with particular knowledge about each individual client. In accordance with the tenets of general systems theory, the goal of nursing practice was balance of the behavioural system. The nurse's role was to foster, protect, sustain, and teach (Campbell, 1987) and thereby bring about not only system balance but also stability and optimal health.

Betty Neuman. Neuman's approach to theorizing about nursing differed from that of other systems theorists in that

it did not rely on concepts concerning needs and drives, nor did it break the system into any component parts. Neuman understood the person to be a physiological, psychological, sociocultural, developmental, and spiritual being (Meleis, 2007) and oriented the attention of the nurse to the “client system” in a health care-oriented and holistic manner (Neuman, 1982). Neuman considered the client system to have innate factors consistent with being human, as well as unique factors that characterized each individual person. According to Neuman, each client had a unique set of response patterns determined and regulated by a core structure. Neuman believed that because the person was vulnerable to environmental stressors, the role of the nurse ought to focus on actual and potential stressors. In this way, Neuman’s model focused on prevention.

Sister Callista Roy. In contrast to most other systems theorists, Roy considered the client not as a behavioural system but rather as an adaptive one. She viewed the person as a biopsychosocial being in constant interaction with a changing environment (Roy, 1984). Her model depicted four modes of adaptation: physiological needs, self-concept, role function, and interdependence (Roy, 1974). She conceptualized the person as an adaptive system with two major internal processes by which to adapt: the cognator and the regulator subsystems (Roy & Andrews, 1999). Roy used these mechanisms to describe and explain the interconnectedness of all aspects of human adaptation and to conceptualize the role of the nurse in managing the stimuli that influence that adaptation (Meleis, 2007).

Simultaneity Theories

The theorists who identified their work as belonging to the simultaneity paradigm considered their theories to be fundamentally distinct from the practice, needs, interactionist, and systems theories. Although simultaneity theories were first articulated long before the paradigm debate arose and before the terms *simultaneity* and *totality* were used to categorize the theories, the language of simultaneity has become prominent in distinguishing this group of nursing theories from others. A characteristic feature of these theories is what Rogers (1970) called the *unitary human being*. Previous theorists had sought to identify aspects of the individual that represented not only an abstract conceptualization of the whole but also provided a comprehensive understanding of the person in terms of his or her parts (such as problems, needs, or goals). In contrast, the simultaneity theorists viewed the individual as an entirely irreducible whole, inherently and “holographically” connected with the universal environment (Parse, 2004). Thus, these theories represented a distinctive approach to articulating an understanding of the client of nursing as well as nursing’s role in relation to that client.

Martha Rogers. Martha Rogers’s (1970) model was revolutionary in presenting the client not simply as a person but as an energy field in constant interaction with the environment, which itself was also an irreducible energy field, coextensive with the universe (Meleis, 2007). According to Rogers, who based her theory on her interpretations of evolving ideas in physics, the role of nursing was to focus on the life process of a human being along a time-space continuum (Rogers, 1970). An early proponent of pattern recognition, Rogers believed that pattern gave the energy field its identity and its distinguishing characteristics (Meleis, 2007). The objective of nursing practice became one of helping clients reach their

maximum health potential in the context of constant change and to develop what Rogers referred to as homeodynamic unity within diversity.

Rosemarie Parse. Parse’s (1981) theory of “man-living-health,” later termed *human becoming* (Parse, 1997), was another view of the individual as a unitary being who is “indivisible, unpredictable, and everchanging” and “a freely choosing being who can be recognized through paradoxical patterns cocreated all-at-once in mutual process with the universe” (Parse, 2004, p. 293). According to Parse’s perspective, the caring presences of nurses and their particular patterns of relating support individuals in the human “becoming” process. Within Parse’s nursing theory, the goal of nursing is articulated not in traditional definitions of health but rather as the notion of people in a continuous process of making choices and changing health priorities. According to Parse’s theory, nurses engage with people in their process of “becoming” through the application of three core processes referred to as explicating, dwelling with, and moving beyond (Parse, 1999).

Jean Watson. Watson (1979) considered the individual to be a totality who can be viewed as a transpersonal self. According to Watson, in contrast to depictions of the individual as a body and an ego, it is more useful to understand the individual as “an embodied spirit; a transpersonal transcendent evolving consciousness; unity of mind body spirit; person-nature-universe as oneness, connected” (Watson, 1999, p. 129). Watson therefore believed that nurses must do far more than deal with physical illness: they must attend to their primary function, which is caring. From Watson’s perspective, caring infuses all aspects of a nurse’s role and draws attention to nursing acts as embodying an aesthetic that facilitates both healing and growth (see Chapter 18).

Each of the models just described attracts continual analysis and implementation. In some instances, nurses draw on them holistically as a coherent approach to guide all of their practices. More often, nowadays, nurses consider themselves informed by the intellectual structure that any good framework provides, but typically expand their thinking beyond the limitations of a single model as their practice develops and progresses.

Theorizing in the Future

Theoretical knowledge leads us to reflect on “the basic values, guiding principles, elements, and phases of a conception of nursing” (Meleis, 2007). The goals of theoretical knowledge are to stimulate thinking and create a broad understanding of the science and practice of the nursing discipline (King & Fawcett, 1997). Although nurses today can appreciate the inherent complexity of these objectives, the creativity and vision modelled by these early theorists continue to inspire theorizing about the essence of nursing.

Nursing is solidly established as a distinct health care discipline with its own unique science. In addition, current theorists draw heavily from philosophy to resolve some of nursing’s theoretical challenges. However, as Kikuchi (1999) pointed out, much of the theorizing about the purpose of nursing has confused rather than clarified thinking. As nursing scholarship evolves to include stronger philosophical and scientific inquiry, nursing practice must be conceptualized with increasing clarity (Silva et al., 1995). Nurse philosophers, as well as scientists, are continuing to use new ways of tackling nursing’s

most complex theoretical feature, which is applying expanding, dynamic, and multiple sources of knowledge to a diverse range of client situations. This problem of understanding the general and applying it to the particular features in the work of many contemporary nursing scholars.

Meleis (1987), a scholar of nursing theory, challenged nurses to direct their theorizing away from the processes by which nurses use knowledge and toward the equally challenging issues associated with the substance of that knowledge. In accepting this challenge, many nursing scholars have shifted their theorizing about nursing to include both theoretical and substantive knowledge. Liaschenko (1997; Liaschenko & Fisher, 1999) oriented this theorizing into three levels of abstraction: knowing the case, knowing the patient, and knowing the person. Engebretson (1997) positioned nursing theory in relation not only to biomedicine but also to Eastern and holistic understandings of health and illness. Starzomski and Rodney (1997) worked toward articulating the link between definitions of health and more philosophical notions of the greater social good. Campbell and Bunting (1991) explored the possibilities of using critical social and feminist theories for emancipatory theorizing in nursing. Watson (1990; see also Brenwick & Webster, 2000) developed the idea of embedding “caring” as a moral component into nursing theory. Yeo (1989) considered the implications of ethical reasoning for nursing theory.

The capacity to provide a rationale for nursing actions and decisions based on theoretical knowledge is a recognized core competency for nursing practice in Canada. However, as this review of the history of theorizing in nursing illustrates, linking theory with practice requires a dynamic and evolving skill set. The inherent complexities underlying interrelationships between theory and practice are therefore of increasing interest to nursing scholars.

A dialogue representing the dynamic interaction between theorizing and clinical practice (often termed **praxis**) has started to emerge (Clarke et al., 1996; Mitchell, 1995; Reed, 1995; Reed & Ground, 1997; Thorne, 1997). This newer form of theorizing does not seek static truths about nursing practice as it considers all truths to be potentially illusory. Rather, it seeks to create a coherent foundation upon which nurses can build, challenge, and integrate an infinite range of new ideas, new forms of knowledge, and new paths toward action. For some theorists, this notion of praxis represents a blend of what has been described as the art and science of nursing (Newman, 2002). For others, it reflects a call to engaging with knowledge in a reflexive manner that invokes emancipation and fuels action (Kagan et al., 2010).

As Levine once wrote, “Theory is the poetry of science” (1995, p. 14). In this manner, theorizing in nursing becomes the engine by which ideas about the discipline are advanced over time. It brings the old and familiar concepts of nursing together and shapes them into bold and exciting new configurations, rendering previously disconnected aspects of the human experience part of a greater whole. In so doing, it makes the intellectual excitement of the discipline come alive.

❖ KEY CONCEPTS

- The hallmark of nursing practice is its unique body of knowledge and the way nurses use it.
- Nursing science has evolved within a historical and social context.

- Nursing theory represents the attempts by nursing scholars to articulate ways in which knowledge from multiple sources can be systematically applied in a wide variety of ways to guide professional, accountable, and defensible nursing practice.
- Much of the early theorizing about nursing practice was specifically designed to guide nursing curriculum development so that nursing education would be focused on the knowledge unique to nursing care.
- The nursing process is the fundamental problem-solving process by which new situations are assessed, plans are developed, and interventions are performed and evaluated.
- Nursing care requires the application of general knowledge to an infinite range of unique situations. Nursing process and nursing theory represent strategies to guide the application process.
- The major components of nursing theory, sometimes called the *metaparadigm concepts*, are person, environment, health, and nursing.
- Nurses' understanding of the role of science has changed as more complex forms of science have been articulated by philosophers of science; science is no longer limited to simple relationships such as cause and effect but instead provides strategies for understanding increasingly complex relationships and phenomena.
- Nursing knowledge derives from various sources in addition to science, including aesthetics, personal knowing, sociocultural understanding, and ethics.
- Nursing theorists based their conceptual frameworks on various ways of thinking about human behaviour and experience. Some framed their ideas within theories of human behaviour, such as needs, interaction, or systems, and others drew their primary inspiration from what they observed in excellent nursing practice.
- Nursing conceptual frameworks include those for understanding both the person as the nurse's client and the nurse's role in relation to that client.
- Although each framework may have attempted to organize nursing knowledge and systematic reasoning processes in a different way, each was aiming for a very similar ideal of excellent decision making in nursing practice.
- Although nursing theoretical frameworks are no longer considered useful as prescriptive models for practice, they provide a way of conceptualizing nursing's interests and of identifying researchable nursing problems.
- As the practice of theorizing about nursing care evolves, the role of philosophy in helping nurses understand their relationship to knowledge has become increasingly relevant.

❖ CRITICAL THINKING EXERCISES

1. How do you think that different ways of conceptualizing the client might influence the kinds of decisions that nurses might make in their practice? Consider how understanding the person in terms of needs, system theory, or interaction might lead you to notice certain things and not others.
2. What sorts of gaps in information or misunderstandings might occur if nurses failed to use a systematic way of thinking about each individual in their care?
3. How do you think that conceptual frameworks and nursing theories might be used to generate research questions for developing knowledge for evidence-informed practice?
4. Why is it useful for nurses to question how they know what they think they know?

❖ REVIEW QUESTIONS

1. A theory is a set of assumptions or propositions that is useful because it
 1. Helps people meet their self-care needs
 2. Isolates concepts
 3. Helps the nurse implement care
 4. Provides a systematic view of explaining, predicting, and prescribing phenomena
2. The drive for early theorizing about nursing practice was derived from
 1. Physicians
 2. Political leaders
 3. Nursing educators
 4. Policymakers
3. The nursing process originally involved which four basic steps?
 1. Assessment, planning, intervention, evaluation
 2. Assessment, nursing diagnosis, planning, intervention
 3. Nursing diagnosis, planning, intervention, evaluation
 4. Planning, assessment, intervention, evaluation
4. The metaparadigm concepts included
 1. The person, environment, health, and nursing
 2. The theories of Thomas Kuhn
 3. Chaos theory and games theory
 4. The grounded theory approach
5. The main question confronting early nursing theorists was about
 1. How to differentiate between nursing theories and medical theories
 2. How to reconcile the generalizations of the North American Nursing Diagnoses Association with the unique situations of each client
 3. How to organize and make sense of general nursing knowledge and apply this knowledge to an individual clinical case
 4. Whether to use theories from other disciplines such as philosophy and to apply them to nursing
6. According to Kuhn, scientific advances happen when creative individuals
 1. Approach a problem in a new way
 2. Use the cause-and-effect model to solve problems
 3. Use the work of other scientists to solve problems
 4. Use empirical evidence to solve problems
7. The McGill model
 1. Focuses on health rather than on illness or treatment
 2. Accounts for holistic aspects of the individual, rather than component parts
 3. Views the person as an energy field in constant interaction with the environment
 4. Considers the human experience to be based on behavioural drives
8. Hildegard Peplau considered the essence of nursing to be
 1. The role of the individual in health maintenance
 2. The relationship between the nurse and patient
 3. Advancing nursing theories
 4. Caring
9. Theorist Evelyn Adam articulated the essence of nursing as
 1. A collaboration with health care providers
 2. A helping process
 3. The management of patients and health care systems
 4. All of the above
10. Systems theorists considered the human being to be
 1. An irreducible whole
 2. A whole and component parts
 3. An embodiment of mind, body, and spirit
 4. All of the above
11. Parse's theory relies on
 1. A traditional definition of illness and health
 2. The idea of people engaging in a continuing process of making choices
 3. The notion of nursing as a caring profession
 4. All of the above

❖ RECOMMENDED WEB SITES

Department of Nursing, Clayton State University School of Nursing, "Nursing Theory Link Page": <http://healthsci.clayton.edu/eichelberger/nursing.htm>

This collection offers links to a wide range of nursing theories, including theories of nursing in general and theories about substantive fields within nursing.

Hahn School of Nursing and Health Science, University of San Diego, "The Nursing Theory Page": <http://www.sandiego.edu/academics/nursing/theory/>

This site orients the student to most of the major nursing theorists and resources to expand an understanding of their contributions.

Research as a Basis for Practice

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by Marilynn J. Wood, BSN, MSN, DrPH, and Wendy Duggleby, RN, PhD, AOCN

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Differentiate evidence-informed practice from traditional practice.
- Identify methods of locating research findings.
- Discuss how to implement evidence-informed practice.
- Identify the various ways to acquire knowledge.
- Discuss methods for developing new nursing knowledge.
- Define nursing research.
- Discuss Canadian nursing research priorities.
- Identify ethical principles important in undertaking research.
- Explain how the rights of human research subjects are protected.
- Explain how to organize information from a research report.

Rick has been a nurse in the emergency department for more than five years. During that time, the nurses have followed a policy of restricting the presence of family members when patients experience critical events that necessitate resuscitation. This policy allows staff to attend to the patient and administer life-saving care without family interference. The nurses have assumed that the experience of watching a loved one undergoing resuscitation is too traumatic for family members. However, Rick has noticed for some time that the families of resuscitated patients experience significant stress when they are unable to stay with their loved one. Later, after the resuscitation, the families may express anger or resentment toward staff. Rick raises a question with the other nurses in the department: "What if we allowed family presence during resuscitation? What would be the outcomes for the families? Is it possible that families can benefit?"

Rick and the other emergency nurses have been practising according to what they know from their education and experience, as well as the policies and practices of

their hospital. This type of practice may not be based on up-to-date information. Current evidence in the scientific literature is that family presence during resuscitation may have distinct benefits. The considerable number of studies that have been done all demonstrate a positive outcome for the family. In spite of the evidence, however, health care practitioners continue to doubt the value of having families remain with the patient (Critchell & Marik, 2007; McGahey-Oakland et al., 2007). This doubt exemplifies the gap between research and practice.

Why Evidence?

The Canadian Nurses Association (CNA) have defined evidence as information acquired through research and scientific evaluation of practice (CNA, 2010). Evidence then is integrated into the decision making of every nurse. Multiple terms are used to describe the utilization of research by nurses in their practice, such as research-based nursing practice, evidence-based practice, evidenced-based decision making, evidence-informed practice, and evidence-informed decision making. Evidence-based practice is the continuous interactive process of consideration of the best available evidence to provide care (CNA, 2010). **Evidence-informed practice** is the integration of the most informative research evidence with evidence from expert clinical practice, client preferences, professional clinical judgement, and other sources to produce the best possible care for clients. As a result, **evidence-informed decision making** provides a safety net for nurses and other health professionals because it enables them to make accurate, timely, and appropriate clinical decisions.

Nursing knowledge must be expanded continuously to keep approaches to nursing care relevant and current. Without new knowledge, nursing cannot improve therapies such as infant care, pain management, grief counselling, or patient education. The major source of new knowledge is research, which can provide a solid foundation for nursing practice. It is important to translate the best evidence into best practices at a patient's bedside. Nurses need a sound knowledge base to support practice, and research is essential for building that knowledge.

Professional nurses must stay informed about current evidence. This is not easy to do. Students may diligently read the assigned materials from texts and articles and assume they have the latest information. A good textbook incorporates evidence into the practice guidelines it describes. However, it takes about two years for a book to be written, published, and in print; therefore, the scientific literature used in the book can be outdated by the time the book is published. Articles, particularly scientific ones, are more likely to be current, but the findings may not be easily applied. They may be inconclusive, or the particular practice that would incorporate the research may not have been studied yet. Moreover, these articles are not readily available to staff nurses at the bedside. It is a distinct challenge to obtain the best, most current evidence when you need it for patient care.

The sources of information about evidence are well-designed, systematically conducted research studies, found in scientific journals; however, nurses currently have limited access to databases for scientific literature. When no evidence is available, tradition prevails.

Nonresearch evidence is another source of information to support practice. This includes quality improvement and risk

> BOX 6-1

Steps for Successful Evidence-Informed Practice

1. Ask a question that clearly presents the clinical problem.
2. Identify and gather the most relevant and best evidence.
3. Critically appraise the evidence.
4. Integrate all evidence with clinical expertise, patients' preferences, and patients' values to make a practice decision or change.
5. Evaluate the outcome of the practice decision or change.

management data; international, national, and local standards; infection control data; chart reviews; and clinical expertise. These sources can be valuable, but their value never approaches that of research evidence.

A third source of evidence that must be incorporated into good clinical decisions consists of individual patients and their values, beliefs, and experience. No efficacious clinical decision can be made without consideration of the uniqueness of the patient.

Much current research focuses on ways to improve the use of new knowledge in practice. Steps to foster success are summarized in Box 6-1.

Researching the Evidence

Ask the Clinical Question

Clinical questions arise out of your practice and represent problems that you wonder about, or things that do not make sense to you. For example, while caring for an unconscious patient, you wonder, "What is the best cleaner to use when I provide mouth care to this patient?" Or you might notice that there has been an increase in patient falls on your unit, leading you to ask, "How can I reduce falls on my unit?"

Clinical questions that arise from your practice should first be addressed by looking to see if the answer is readily available: "What is the current evidence to improve pain management in patients with migraine headaches?" Important sources of this type of information can be found in practice guidelines available from professional associations. All professions have focused on ensuring that service professionals understand practice guidelines. "Best practices" are guiding principles leading to the most appropriate courses of action in certain standard practice situations. They are based on the accumulated research findings, as well as on evidence from practice. This sets best practices apart from the much more general nursing practice standards. Since 1999, the Ontario Ministry of Health and Long-Term Care has given substantial annual funding to the Registered Nurses' Association of Ontario (RNAO) for a project to develop, vet, and disseminate "best practice guidelines" that identify actions in particular patient situations. This is a multiyear project to assist nurses in providing informed and high-quality care (RNAO, 2011). These guidelines are available to all Canadian nurses (Box 6-2).

The questions you ask will eventually lead you to the evidence required for an answer. When you consult the scientific literature for an answer, you want to read the most informative

four to six articles that address your practice question specifically, not be mired in hundreds of articles that might have some relationship to your question. This means that your question must be well stated and focused on just the relevant components of the issue (Stillwell, 2010). Unfocused questions ("What is the best way to reduce wandering?" "What is the best way to measure blood pressure?") are too vague and will lead to many irrelevant sources of information. Melnyk and Fineout-Overholt (2005) suggested using a "PICO" format to state your question. A PICO question has four components: P = Patient population of interest: What are the age, gender, ethnicity, and disease or health problem of the patients? I = Intervention of interest: What is the best intervention (treatment, diagnostic test, prognostic factor)? C = Comparison of interest: What is the usual standard of care or current intervention used now in practice? O = Outcome: What result (e.g., change in patient behaviour, physical finding) do you want to achieve as a result of the intervention?

Do not be satisfied with clinical routines if they do not improve the patient's quality of life. Always question and use critical thinking to consider better ways to provide patient care. The questions you raise by using a PICO format help you identify knowledge gaps within a clinical situation and assist you in making sound clinical decisions for change.

Collect the Best Evidence

Once you have a clear and concise PICO question, you are ready to search for evidence. You can find the evidence you need in a variety of sources: agency policy and procedure manuals, quality improvement data, existing clinical practice guidelines, or bibliographical databases. Always ask for help to find appropriate evidence. Nursing faculty are always a key resource, as are advanced practice nurses, staff educators, and infection control nurses.

When you go to the literature for evidence, a librarian can help you to locate the appropriate databases (Box 6-3). The databases contain published scientific studies, including peer-reviewed research. An article that has undergone peer review has been reviewed by a panel of experts before publication. The search process requires you to come up with keywords or phrases from your PICO question that most accurately describe what you want from the search. The librarian can help you find the language that yields the most informative results. You usually need to adjust the wording of your search criteria until you get the results you want.

The best-known databases for nursing literature are MEDLINE and CINAHL. These are comprehensive databases containing articles from most nursing and health journals. These are usually available at no cost to students through the university or college library.

The pyramid in Figure 6-1 represents the hierarchy of available evidence. At the top of the pyramid are systematic reviews and meta-analyses. These reviews have been conducted by experts in the clinical area, who review the evidence about a specific clinical question or issue and summarize the state of the science. Of primary importance in these reviews are the randomized controlled trials (RCTs) that have been conducted on the topic. On occasion, they include other types of research as well. Later in this chapter, the research process is examined more carefully, and you will find that the majority of nursing research is not at the level of the RCT. Nevertheless, the RCT is considered the "gold standard" in scientific research,

Levels of Research Evidence

intervention in managing the blood glucose levels of patients with newly diagnosed diabetes.

Critique the Evidence

The most difficult step in the evidence-informed practice process probably is critiquing or analyzing the available evidence. The critiquing of evidence involves determining its value, feasibility, and utility for changing practice. When you critique evidence, first evaluate the scientific merit and clinical applicability of each study's findings. Then, with a group of studies and expert opinion, determine what findings have a strong enough basis for use in practice. After critiquing the evidence, you will be able to answer the questions, Do the articles together offer evidence to explain or answer your PICO question? Do the articles show that the evidence is true and reliable? Can you use the evidence in practice? Because you are a student and new to nursing, it will take time to acquire the skills to critique evidence like an expert. When you read an article from the literature, do not let the statistics or technical wording cause you to stop reading the article. Know the elements of an article, and use a careful approach when you review each one. Evidence-informed articles include the following elements:

- **Abstract:** An abstract is a brief summary of the article that quickly tells you whether the article is research or clinically based. An abstract summarizes the purpose of the study or clinical query, the major themes or findings, and the implications for nursing practice.
- **Introduction:** The introduction contains information about the purpose of the article and the importance of the topic for the audience who reads the article. Brief supporting evidence is usually presented as to why the topic is important from the author's point of view. Together, the abstract and introduction tell you whether you want to read the entire article. You will know if the topic of the article is similar to your PICO question or related closely enough to provide you with useful information. Continue to read the next elements of the article.

in which the effect of a specific treatment or intervention is tested through the use of experimental and control groups. A systematic review of RCTs in which an intervention (such as computerized interactive patient teaching) is used would answer a PICO question about the effectiveness of this

- *Literature review or background:* A useful article has a detailed background of the existing level of science or clinical information about the topic of the article. Therefore, it offers an argument about what led the author to conduct a study or report on a clinical topic. This section of an article is valuable. Perhaps the article itself does not address your PICO question in the way you desire, but it may lead you to other articles that are more useful. A literature review of a research article indicates how past research led to the researcher's question. For example, an article about a study designed to test an educational intervention for older adult family caregivers reviews literature that describes characteristics of caregivers, the type of factors influencing caregivers' ability to cope with stressors of caregiving, and any previous educational interventions used with families.
- *Manuscript narrative:* "Middle sections," or narratives, of articles differ according to the type of evidence-informed article they are (Melnik & Fineout-Overholt, 2005). A clinical article describes a clinical topic and often includes a description of a patient population, the nature of a certain disease or health alteration, how patients are affected, and the appropriate nursing therapies. Some clinical articles explain how to use a therapy or new technology. A research article will contain several subsections within the narrative, including the following.
 - *Purpose statement:* A purpose statement explains the focus or intent of a study. It identifies what concepts were researched. This includes research questions or hypotheses: predictions made about the relationship or difference between study variables (concepts, characteristics, or traits that vary within or among subjects). An example of a research question is as follows: "What characteristics are common among older adults who have annual breast screening?"
 - *Methods or design:* The methods or design section explains how a research study is organized and conducted in order to answer the research question or to test the hypothesis. This explanation includes the type of study to be conducted (e.g., RCT, case control study, or qualitative study) and how many subjects or persons are in a study. In health care studies, "subjects" may include patients, family members, or health care staff. The language in the methods section is sometimes confusing because it contains details about how the researcher designs the study to minimize bias and thereby obtain the most accurate results possible. Use your faculty member as a resource to help interpret this section.
 - *Results or conclusions:* Clinical and research articles have a summary section. A clinical article explains the clinical implications for the topic presented, whereas a research article details the results of the study and explains whether a hypothesis is supported or how a research question is answered. If the study is quantitative, this section includes a statistical analysis. For a qualitative study, the article presents a thorough summary of the descriptive themes and ideas that arise from the researcher's analysis of data. Do not be stumped by the statistical analysis in an article. Read carefully, and ask whether the researcher describes the results and whether the results were significant. Have a faculty member assist you in interpreting statistical results. A helpful results section also discusses any limitations to a study. This information on limitations is valuable in helping you decide whether you want to use the evidence with your patients.

- *Clinical implications.* A research article includes a section that explains whether the findings from the study have clinical implications. This section also explains how to apply findings in a practice setting for the type of subjects studied. After you have critiqued each article for your PICO question, synthesize or combine the findings from all of the articles to determine the state of the evidence. Use critical thinking to consider the scientific rigour of the evidence and how well it answers your area of interest. Consider the evidence in view of your patients' concerns and preferences. Your review of articles offers a snapshot conclusion that is based on combined evidence about one focused topical area. As a clinician, judge whether to use the evidence for a particular patient or group of patients, who usually have complex medical histories and patterns of responses (Melnik & Fineout-Overholt, 2005). It is ethically important to consider evidence that benefits patients and does no harm. Decide whether the evidence is relevant, is easily applicable in your setting of practice, and has the potential for improving patient outcomes.

Integrate the Evidence

Once you decide that the evidence is strong and applicable to your patients and clinical situation, incorporate the recommended evidence into practice. Your first step is to simply apply the research in your plan of care for a patient. Use the evidence you find as a rationale for an intervention you plan to try. For instance, you learned about an approach for bathing older adults who are restless, and you decide to use the technique during your next clinical assignment. You use the bathing technique with your own assigned patients, or you work with a group of other students or nurses in revising a policy and procedure or in developing a new clinical protocol. In another example, after being concerned about the rate of intravenous catheter dislodgement, you consult the evidence to compare the efficacy of gauze dressings with that of transparent dressings. The literature suggests that fewer catheter dislodgements occur with transparent dressings on peripheral intravenous sites than with gauze dressings, with no increase in phlebitis or infiltration rates (Melnik & Fineout-Overholt, 2005). As a result of your findings, you meet with the policy and procedure committee of your institution to recommend the use of transparent dressings routinely. You then implement the use of transparent dressings in the routine care of peripheral intravenous catheters.

Evidence is useful in a variety of ways in formulating teaching tools, clinical practice guidelines, policies and procedures, and new assessment or documentation tools. Depending on the amount of change needed to apply evidence in practice, it becomes necessary to involve a number of staff from a given nursing unit. It is important to consider the setting in which you want to apply the evidence: Do all staff members support the change? Does the practice change fit with the scope of practice in the clinical setting? Are resources (time, administrative support, and staff) available to make a change? When evidence is not strong enough to apply in practice, your next option is to conduct a pilot study to investigate your PICO question. A pilot study is a small-scale research study or a study that includes a quality or performance improvement project. As a nursing student integrating evidence, your study begins with searching for and applying the most useful evidence to improve the care you provide directly to your patients. The evidence available within nursing literature gives you an

almost unlimited access to innovative and effective nursing interventions. Using an evidence-informed practice approach helps you improve your skills and knowledge as a nurse and improve outcomes for your patients.

Evaluate the Practice Decision or Change

After applying evidence in your practice, your next step is to evaluate its effect. How does the intervention work? How effective was the clinical decision for your patient or practice setting? Sometimes your evaluation is as simple as determining whether the expected outcomes you set for an intervention are met. For example, after the use of a transparent intravenous dressing, does the catheter dislodge, or does the complication of phlebitis develop? When you use a new approach to preoperative teaching, does the patient learn what to expect after surgery?

When an evidence-informed practice change occurs on a larger scale, an evaluation is more formal. For example, evidence of factors that contribute to pressure ulcers might lead a nursing unit to adopt a new skin care protocol. To evaluate the protocol, the nurses track the incidence of pressure ulcers over a course of time (e.g., six months to a year). In addition, the nurses collect data to describe both the patients who develop ulcers and those who do not. This comparative information is valuable for determining the effects of the protocol and whether modifications are necessary.

Support for Evidence-Informed Practice

Nursing practice is based on theory, professional values, and evidence. Nurses base decisions on these factors, as well on other influences such as individual values, ethics, legislation, patient choice, and practice environments. The CNA position statement on evidence-informed decision making specifies its importance in providing quality nursing care, and in effecting change across the health care system. The evidence to be used in practice is derived through research and the scientific evaluation of practice. Types of evidence include experimental studies of nursing interventions, meta-analysis of groups of studies on a particular topic, nonexperimental or observational studies, expert opinion through consensus documents, and historical information. The CNA believes that individual nurses must read and critique evidence-informed literature in order to provide high-quality care to clients (CNA, 2010).

Knowledge Development in Nursing

Knowledge that provides the rationale for nursing practice is organized in a variety of ways. In her classic article on patterns of knowing in nursing, Carper (1978) identified four patterns: “empirics,” or the science of nursing; esthetics, or the art of nursing; personal knowing; and ethics, or the moral component. A fifth type of knowing, emancipatory knowing, was later added by Chinn and Kramer (2008) (Table 6-1). These different types of knowledge focus on the meaning and value of nursing expertise. With evidence-informed practice, the evidence can be derived from any of these sources of knowledge.

Empirics: The Science of Nursing

Carper (1978) described empirics as “knowledge that is systematically organized into general laws and theories for the

► TABLE 6-1

Fundamental Patterns of Knowing in Nursing

Empirics: the science of knowledge	Knowledge developed through systematic research to describe and explain phenomena
Esthetics: the art of nursing	Creativity, with an artistic or expressive component
Personal knowledge	Knowledge derived from the depth and power of the interpersonal relationship with the patient
Ethics: the moral component	Knowledge that emerges from ethical dilemmas and is based on what ought to be done in particular situations
Emancipatory knowing: the social, economic, and political component	Knowledge that allows change to occur

From Carper, B. A. (1978). Fundamental patterns of knowing in nursing. *Advances in Nursing Science*, 1(1), 13; and Chinn, P., & Kramer, M. (2008). *Integrated theory and knowledge development in nursing* (p. 78). St Louis, MO: Mosby/Elsevier.

purpose of describing, explaining and predicting phenomena of special concern to the discipline of nursing” (p. 14). This pattern of knowing implies an objective reality; by studying this, you can interpret the meaning of particular phenomena and develop understandings of other similar phenomena. Fundamental to this model is the rational stance in which you can generalize from a sample to a population. The theoretical or conceptual models and frameworks help explain particular phenomena in health and illness and identify important questions for nursing research. The goal of scientific research is to produce this type of knowledge.

Esthetics: The Art of Nursing

Nursing incorporates an artistic, expressive component, which involves knowledge and understanding. As Carper (1978) noted, “The art of nursing involves the active transformation of the patient’s behavior into a perception of what is significant in it—that is, what need is being expressed by the behavior” (p. 17). She further stated that perception is beyond mere recognition and, as such, moves nursing activities into the esthetic realm. Qualitative research often explores this area.

Personal Knowledge

This pattern of knowing can be the most difficult to understand and to teach. The nature of the relationship formed with the patient and the depth and quality of the interpersonal experience are fundamental to the realm of personal knowledge. As Carper (1978) stated, “Personal knowledge is concerned with the knowing, encountering and actualizing of the concrete, individual self” (p. 18). Many investigators have attempted to understand the nature of therapeutic relationships. Through the rapport established with the patient, how does a nurse succeed in assisting that patient to reach health goals? Perhaps “the nurse in the therapeutic use of self rejects approaching the patient-client as an object and strives instead to actualize an authentic personal relationship between two persons” (Carper, 1978, p. 19). The knowledge gleaned from experience belongs to this pattern.

Ethics: The Moral Component

Nurses are faced with ethical questions that centre on what ought to be done in particular situations. Ethics goes beyond ethical theories, principles, and codes of professional conduct to include dilemmas such as choosing the better of two or more somewhat unsatisfactory actions. Now that technology can prolong life, ethical dilemmas have become more frequent and complex. As Carper (1978) stated, "The ethical pattern of knowing in nursing requires an understanding of different philosophical positions regarding what is good, what ought to be desired, and what is right; of different ethical frameworks devised for dealing with the complexities of moral judgements; and of various orientations to the notion of obligation" (p. 21).

Emancipatory Knowing: The Social, Economic, and Political Component

Emancipatory knowing makes it possible to create social and structural change (Chinn & Kramer, 2008). It represents the ability to recognize social and political problems of injustice or inequity, to picture how things could be different, and to figure out how to change a difficult situation into one that improves the lives of people. Nurses have dealt with emancipatory knowledge since the nineteenth century, when Florence Nightingale wrote passionately about the inequities in society affecting women. As described by Chinn and Kramer, "Emancipatory knowing is the capacity not only to notice injustices in a social order, but also to critically examine why injustices seem not to be noticed or remain invisible, and to identify social and structural changes that are required to right social and institutional wrongs" (p. 78).

Nurses benefit from all these ways of knowing. According to the concept of evidence-informed practice, evidence gained from any and all of these means guides nurses to make sound clinical decisions. The knowledge gained from empirics is but one pattern of knowledge, but with it, you can build strength and confidence as you pursue research into nursing questions.

The Development of Research in Nursing

Research is the primary means by which new knowledge is discovered and brought into practice to improve the care that nurses provide to their patients. It is a systematic process in which questions that generate knowledge are asked and answered. This knowledge becomes part of the scientific basis for practice and may be used to validate interventions.

Nursing research is a systematic examination of phenomena important to the nursing discipline, as well as to nurses, their patients, and families. Its purpose is to expand the knowledge base for practice by answering nurses' questions. Nursing research addresses a range of issues related to actual and potential patient populations and to individual and family responses to health problems. Some research tests nursing theories; other research generates theory from findings. This "back-and-forth" relationship between theory and research is the way knowledge develops in any discipline (Wood & Ross-Kerr, 2011). In the current health care environment, nursing research is frequently undertaken in multidisciplinary teams, in which nurses examine factors relevant to nursing in the context of the larger health care picture. The scientific knowledge needed for nursing practice is discovered, tested, and enhanced through nursing research. The multidisciplinary

nature of nursing challenges nurses not only to keep up with nursing research but also to know the status of research in other health disciplines, as well as in the behavioural, social, and physical sciences.

The International Council of Nurses (ICN) (ICN, 2007) is a staunch supporter of nursing research as a means to improve people's health and welfare. Research is a way to identify new knowledge, improve education and practice, and use resources effectively. In 1999, the ICN established the ICN Research Network. The network provides a means for sharing research ideas, results, and progress around the world. Network members communicate with one another through the ICN Web site, as well as at annual conferences.

Nursing research improves nursing practice, raising the profession's standards. Involvement in research takes many forms, including designing studies, being on a research team, collecting data, and using research findings to change clinical practice, improve patient outcomes, and contain health care costs (Cleary-Holdforth, 2009). Promoting research and using it in practice increases the scientific knowledge base for nursing practice. Patients benefit from these improvements to practice.

The History of Nursing Research in Canada

During the Crimean War, Florence Nightingale's detailed and systematic observation of nursing actions and outcomes resulted in major changes in nursing practice (Box 6-4). Her work demonstrated the importance of systematic observational research to nursing practice.

In Canada, the establishment of university nursing courses starting in 1918, followed by master's degree programs in the 1950s and 1970s and by doctoral programs in the 1990s and 2000s, was crucial to the development of nursing research. The first master's degree program, established at the University of Western Ontario in 1959, highlighted the need for Canadian research capacity in nursing.

The first nursing research journal, *Nursing Research*, was launched in the United States in 1952. The first nursing research journal published in Canada, *Nursing Papers* (later the *Canadian Journal of Nursing Research*), was established at McGill University in 1969. Other journals were later established, and today, nurses publish their research, both within nursing and in interdisciplinary fields, in hundreds of journals.

Since the 1970s and 1980s, the two major factors in the development of nursing research have been the establishment of research training through doctoral programs and the establishment of funding to support nursing research. Throughout the 1970s and 1980s, university faculties and schools of nursing built their research resources so that they could establish doctoral programs. The first provincially approved doctoral nursing program was established at the University of Alberta Faculty of Nursing in 1991. Another was established at the University of British Columbia School of Nursing later that year, and programs at McGill University and the University of Toronto followed in 1993. Between 1993 and 2008, other programs were launched, which brought the total across Canada to 12.

Growing awareness of the importance of nursing research gradually led to the availability of research funds. The year 1964 marked the first time that a federal granting agency funded nursing research in Canada (Good, 1969). In 1999, 14 years after the U.S. government had established funding for

► BOX 6-4 Historical Milestones in the Development of Canadian Nursing Research

1858	Florence Nightingale published <i>Notes on Matters Affecting the Health, Efficiency and Hospital Administration of the British Army and Notes on Hospitals</i> (1863).	1990	Francine Ducharme was the first nurse to graduate with a PhD in nursing from a Canadian university, through a special case program at McGill University.
1918	The University of British Columbia launched the first baccalaureate nursing program in Canada.	1991	The first Canadian nursing PhD program was launched at University of Alberta, followed by one at University of British Columbia.
1952	The American Nurses Association first published the journal <i>Nursing Research</i> .	1992–1994	PhD programs in nursing were launched at McGill University, University of Toronto, and McMaster University.
1959	The first Canadian nursing master's degree program was launched at the University of Western Ontario.	1992	The MRC mandate was revised to include health research.
1964–1965	The first nursing research project was funded by a Canadian federal granting agency; the <i>International Journal of Nursing Studies</i> and <i>International Nursing Index</i> were launched.	1999	The Nursing Research Fund was launched with a \$25-million grant over 10 years; the Canadian Health Services Research Foundation administered the funds. PhD program in nursing was launched at the University of Calgary.
1969–1970	Nursing Papers, forerunner of the <i>Canadian Journal of Nursing Research</i> , was published at McGill University; Lysaught's (1970) report, <i>An Abstract for Action</i> , recommending increased research in education and practice, was published.	2003–2008	PhD programs in nursing were initiated at Dalhousie University, the University of Victoria, the University of Western Ontario, the University of Ottawa, l'Université Laval, and l'Université de Sherbrooke.
1971	McGill University launched the Centre for Nursing Research; the first national Canadian conference was held on nursing research; both were financed by the Department of National Health and Welfare.	2004	A forum on doctoral education was held in Toronto under the auspices of Canadian Association of Schools of Nursing to develop a national position paper on the PhD in nursing for Canada.
1975	The Commission on Canadian Studies noted that the slow start of graduate programs in Canada and inadequate funding, resulted in few studies in nursing.	2007	<i>Nursing Research in Canada: A Status Report</i> was commissioned by the Canadian Consortium for Nursing Research, which included representatives from Canadian Nurses Association, Canadian Association of Schools of Nursing, Canadian Nurses Foundation, Academy of Canadian Executive Nurses, and the Canadian Association of Nurse Researchers. This report made recommendations for the future of nursing research.
1978	The heads of university nursing schools and deans of graduate studies attended the Kellogg National Seminar on Doctoral Education in Nursing.	2008	The first nurse researcher was appointed as scientific director of the CIHR Institute of Gender and Health. Dr. Joy Johnson works with the Canadian gender, sex, and health research community and stakeholders to identify research priorities, develop research funding opportunities, strengthen research capacity, build partnerships, and translate research evidence to improve the health of Canadians.
1982	The Alberta Foundation for Nursing Research, the first funding agency for nursing research, was established; the Working Group on Nursing Research was established by the Medical Research Council (MRC).		
1985	<i>Report of the Working Group on Nursing Research</i> was released by the MRC (Medical Research Council of Canada, 1985).		
1988	The MRC and the National Health Research and Development Program established a joint initiative to structure nursing research grants.		

nursing research under the National Institutes of Health, the Canadian government established the Nursing Research Fund, budgeting \$25 million for nursing research (\$2.5 million over each of the following 10 years); the funds were to be administered by the Canadian Health Services Research Foundation. The research areas targeted for support included nursing policies, management, human resources, and nursing care. A total of \$500,000 each year is designated for the Open Grants Competition, \$500,000 to the Canadian Nurses Foundation for research on nursing care, \$750,000 for training (postdoctoral fellowships and student grants), and \$250,000 for knowledge networks and dissemination activities. Five chairs in nursing research, representing excellence in nursing research across Canada, were funded by this initiative. The incumbents were to develop research capacity in a particular area of nursing:

- Dr. Lesley Degner, University of Manitoba: Development of Innovative Nursing Interventions to Influence Practice

and Policy in Cancer Care, Palliative Care, and Cancer Prevention

- Dr. Alba Dicenso, McMaster University: Evaluation of Nurse Practitioner/Advanced Practice Nurse Roles and Interventions
- Dr. Nancy Edwards, University of Ottawa: Multiple Interventions in Community Health Nursing Care
- Dr. Janice Lander, University of Alberta: Evaluating Innovative Approaches to Nursing Care
- Dr. Linda O'Brien-Pallas, University of Toronto: Nursing Human Resources for the New Millennium

Nursing research has focused progressively on evidence-informed practice in response to demands to justify care practices and systems by improving patient outcomes and controlling costs. The scope of nursing research has also broadened to include historical and philosophical inquiry. The establishment of the Institute for Philosophical Nursing

Research at the University of Alberta and the Nursing History Research Unit at the University of Ottawa exemplify this new direction.

Three new training centres funded by the Nursing Research Fund at the Canadian Health Services Research Foundation were mandated to increase research capacity in nursing and related disciplines:

- The Centre FERASI (<http://www.ferasi.umontreal.ca>) in Quebec is a joint initiative among l'Université de Montréal, McGill University, and l'Université Laval to build research capacity in the administration of nursing services. It focuses on developing partnerships with health care decision makers in order to provide training opportunities and insights into the decision-making environment. Funding is provided for student scholarships.
- The Ontario Training Centre in Health Services and Policy Research (<http://www.otc-hsr.ca>) involves six Ontario universities in enhancing health services and policy research. The centre is located at McMaster University and involves collaboration with the University of Toronto, York University, the University of Ottawa, Laurentian University, and Lakehead University.
- The Centre for Knowledge Transfer was designed as a national training centre at the University of Alberta, providing funding for students and offering courses in knowledge utilization and transfer. This centre is now closed.

Nursing Research

In a mature discipline, practitioners use various research methods to develop a unique knowledge base (Wood and Ross-Kerr, 2011). A person continuously acquires knowledge, using critical thinking to interpret and evaluate complex information. Current research can be classified into one of two ways of thinking: scientific or qualitative (interpretive). Both have a great deal to offer when you are seeking evidence to support your practice.

The Scientific Paradigm

The term *paradigm* was introduced by Kuhn (1970) and can be loosely defined as a way of thinking (see Chapter 4). According to Kuhn, a dominant research paradigm can be identified

during any one era. Eventually, this paradigm no longer provides solutions to research problems and is challenged by new ideas. It is then replaced by a new paradigm, and the process continues. The dominant paradigm for most of the nineteenth and twentieth centuries has been positivism. Positivism emphasizes tested and systematized experience, rather than speculation, and focuses on the search for cause-and-effect relationships to explain phenomena. In this paradigm, the **scientific method** arose as the major research approach.

Researchers who use the scientific method pose research questions and collect and analyze data to find answers to the questions. The process is rigorous and systematic and is guided by scientific principles, the most important of which is empiricism, which means that only things that can be observed by the human senses can be called *facts*. The focus is on deductive reasoning, in which a **hypothesis** is tested experimentally to confirm or reject theoretical explanations of phenomena.

The scientific method is characterized by systematic, orderly procedures that, although not without fault, are intended to limit the possibility of error and minimize the likelihood that any bias or opinion by the researcher might influence the results of research and, thus, the knowledge gained. Wood and Ross-Kerr (2011) describe the **research process** as follows: the process begins with a researchable question. If properly stated, the question guides the rest of the process; thus, asking the question is a crucial step. Three levels of questions exist, and the appropriate level is chosen based on how much is known about the research topic. Once an initial question has been formulated, the literature is searched to discover what is already known about the topic and to determine whether the question must be revised in light of prior knowledge. The level of the question determines the research design needed to answer it. Table 6-2 describes the basic steps in planning nursing research.

The research design provides the ground rules for data collection and analysis, ensuring that the research question will have a valid answer. The design steps are systematic and precise in order to control unwanted influences that might affect the answer. For example, in a study of the relationship between diet and heart disease, influences such as stress or smoking must be controlled because they are known to

► TABLE 6-2 Basic Steps in Planning Nursing Research

Steps	Level I	Level II	Level III
Question	What?	What is the relationship?	Why?
Problem	Little known about topic	Conceptual base; variables have been studied before	Theoretical base
Purpose	Declarative statement	Question or hypothesis	Hypothesis
Design	Exploratory descriptive	Descriptive survey, correlational or comparative	Experiment
Sample	Convenience sample or total population	Probability sample	Random assignment to treatment and control groups
Methods	Qualitative, unstructured data; some quantitative descriptive data	Quantitative data collected by all methods	Quantitative data
Analysis	Content analysis; descriptive statistic	Correlation or tests of association; regression analysis	Differences between means: test, analysis of variance (ANOVA)
Answer	Description of processes, concepts, or population	Explanation of relationship among variables	Test of theory

Adapted from Wood, M., & Ross-Kerr, J. (2011). *Basic steps in planning nursing research: From question to proposal*. Sudbury, MA: Jones & Bartlett.

influence heart disease. The design also specifies the type of sample and sample selection techniques that will provide the most useful data for the study.

Evidence that is part of experience (**empirical data**) is gathered from the sample through measurement techniques that quantify the variables in the research question. Techniques include interviews, tests of knowledge, and physiological measures such as heart rate and blood pressure. When the evidence is analyzed, the result answers the original question and becomes the basis for discovering new knowledge.

A goal of scientific research is to understand phenomena so that the knowledge gained can be applied generally, not just to isolated cases. Researchers achieve this goal by studying a sample that represents a larger population; this increases the likelihood that the results will apply across that population. In the scientific paradigm, researchers conduct studies that contribute to the testing or development of theories, thereby advancing knowledge that can be applied in nursing practice.

The Qualitative (Interpretive) Paradigm

Positivism has been criticized by those academics who believe that reality and people's perception of reality are so intertwined that they cannot be separated. Interpretivism is an alternative to positivism, representing the view that people construct their own world as they strive to make sense of their social environments (Speziale et al., 2010). The research that is driven by interpretivism can be broadly designated *qualitative research*. Qualitative research avoids the empirical notion of the study of people as objects and strives instead to understand human behaviour in the context of the people being studied. A qualitative researcher studies the behaviours, experiences, perceptions, and motives of individuals in social and cultural settings (Speziale et al., 2010).

Several approaches to qualitative research exist, and each is very different from the others. Unlike the scientific approach, many qualitative approaches have their own unique philosophical base, which makes comparisons difficult. Speziale et al. (2010, p. 21) identified the following six characteristics common to all qualitative research:

- Belief in multiple realities
- Commitment to identifying an approach to understanding that will support the phenomenon studied
- Commitment to the participant's point of view
- Conduct of inquiry in a way that does not disturb the natural context of the phenomena of interest
- Acknowledged participation of the researcher in the research
- Conveyance of the understanding of phenomena by reporting in a literary style rich with participants' commentary

The idea of multiple realities is a challenge to positivist thinking, which proposes that researchers are searching for one reality or truth. Interpretivists say that because the experience of each individual is unique, each individual can come to know the world differently, which implies that many truths exist, rather than one. This belief leads qualitative researchers to seek multiple ways of understanding the world and to change methods and data collection strategies as needed, rather than following a single prescribed set of strategies. It follows that the participant's point of view would be the focus of the research and would guide the process. The researcher becomes a co-participant in the process of understanding the participant's point of view.

Qualitative research is carried out in the participants' natural setting to maintain a natural context. The researcher is a participant and acknowledges that being a participant will affect the other participants and the setting. Objectivity is not a goal in qualitative research; rather, subjectivity from the participants' perspective is sought. Because of the nature of the data, rich with personal experience and example, the research is usually reported in a literary style, similar to storytelling. Liberal quotation from the participants adds to the detail of the report.

Research Designs

Nursing research approaches vary, depending on the specific problem to be studied. The paradigms of positivism and interpretivism lead to two research approaches, often categorized as quantitative and qualitative. Neither is used exclusively in nursing research. The research approach used is the one that is considered the best one to answer the research question. The next section describes some common research designs in these two categories.

Quantitative Nursing Research

Quantitative nursing research is the investigation of nursing phenomena that can be precisely measured and quantified. Examples are pain severity, rates of wound healing, and body temperature changes. These designs fall within the positivist paradigm and provide rigorous, systematic, objective examination of specific concepts and their relationships. The goal is to test theory and use numerical data, statistical analysis, and controls to eliminate bias (Polit & Beck, 2010; Wood & Ross-Kerr, 2011).

Experimental Research. Experimental design is the hallmark of quantitative research. Experiments are appropriate designs for questions at level III (see Table 6-2), which concern why one variable causes a predictable change in another variable. In a **true experiment**, the conditions under which the variables are studied are tightly controlled to provide objective testing of hypotheses, which predict cause-and-effect relationships. Experimental research requires that the data be collected and quantified in a prescribed manner.

The requirements of a true experiment are as follows:

- The study usually includes at least one control or comparison group that does not receive the nursing treatment or intervention being investigated. The results for this group are compared with those of the experimental group, which is the group that receives the treatment or intervention. The **subjects**—people selected for the comparison and experimental groups—are randomly assigned to these groups, so that the groups are as similar as possible to each other before the intervention. Random assignment of subjects ensures that all subjects have the same chance to be in the control or experimental (treatment) group and that variables that could affect the outcome of the study are randomly distributed between the groups and therefore are no more likely to affect experimental subjects than to affect control subjects.
- An experimental variable must be manipulated by the researcher. For example, in a study of the effect of preoperative teaching on postoperative anxiety, the researcher manipulates preoperative teaching by providing it for the experimental group but not for the control group. The expectation is that the differences in postoperative anxiety

measures between the two groups can be attributed to the effect of preoperative teaching because all other factors are under control. However, the researcher cannot control subjects' prior experiences, such as hearing other patients' stories about surgery. Psychological factors, which cannot be controlled, may influence a subject's level of anxiety. If subjects are randomly assigned to the two groups, however, those with negative prior experiences should be distributed equally between the two groups, and these experiences would affect both groups equally. Thus, differences between the groups in postoperative anxiety can still be attributed to the preoperative teaching intervention.

- The researcher proposes theory-based and statistically tested hypotheses about the action of the variables to answer the research question. For example, in a study of preoperative teaching, the hypothesis might be as follows: "Patients who receive interactive preoperative teaching will have significantly lower postoperative anxiety levels than will patients who receive other teaching methods." The researcher must explain why a lower anxiety level is expected in a discussion of the theory behind the study.

A **quasi-experimental research design** is one in which groups are formed and the conditions are controlled, but the subjects are not randomly assigned to a control group or to treatment conditions. These designs also answer level III questions (Wood & Ross-Kerr, 2011). In many health care settings, assigning subjects randomly to experimental and control groups is not feasible. Quasi-experimental research is often carried out for practical reasons related to the subjects themselves. For example, to test the effect of a new intervention in the care of patients with Alzheimer's disease, carrying out two treatments on the unit at the same time might confuse the subjects. A quasi-experiment could entail the use of two care units: one as the experimental unit, in which all subjects receive the new intervention, and the second as the control group, in which subjects receive the usual care but not the new intervention. The two groups are compared before and after the intervention with regard to the outcome variable. The weakness in a quasi-experiment is that the researcher does not know whether the two groups were equivalent before the intervention. Unrecognized differences between the two units might exist that could influence the outcome of the study. For instance, subjects in one unit might have more cognitive impairment than do those in the other unit, and this difference could influence the outcome.

Descriptive Survey Designs. Surveys are designed to answer level II questions about relationships among variables. The research question that leads to a survey design begins with "What is the relationship between . . . ?" and addresses two or more variables (Wood and Ross-Kerr, 2011): for example, the relationship between ethnicity and suicide among university students.

In many types of research, investigators use surveys in which people in a group are compared with regard to two or more variables. The purpose is to discover relationships among variables in the population. In a survey design, the sample determines whether the survey yields informative or uninformative results. The sample should be representative of the population so that generalizations can be made on the basis of the sample data. Surveys contain three key elements. First, a random sample of the population must be drawn, from which inferences can be made about the population. Second, the population sampled should be large enough to keep sampling

error to a minimum. Third, the measurement tools (e.g., questionnaires, interviews) must yield accurate measurements of the study variables.

Exploratory Descriptive Designs. Exploratory descriptive designs provide in-depth descriptions of populations or variables not previously studied. Level I (basic) questions are asked because not much is known about the topic. They typically begin with "what"; for example, "What are the health-promoting behaviours of older adults living in subsidized housing?" The results provide a detailed description of the variable or population. No relationships among variables are posited at this stage, although the results might indicate that relationships should be examined in subsequent research.

Data Analysis. Except for some exploratory descriptive studies in which the outcome is a verbal description, all quantitative studies entail the use of statistical analysis. In experimental designs, researchers must discover whether the experimental and control groups are significantly different from each other after the intervention has been applied. Statistical tests that provide a test of group means are generally used for experiments.

Descriptive survey designs entail the use of statistical techniques to test for significant relationships among the variables. In general, these are correlational tests that indicate whether one subject's score on one variable (e.g., blood pressure) is related to the same subject's score on another variable (e.g., weight). The results of a correlational analysis of these two variables would reveal how much influence increased body weight has on blood pressure.

Exploratory descriptive studies entail the use of several techniques to analyze data, depending on the type collected. Unstructured data that do not lend themselves to numerical form are summarized verbally. If quantitative measures are used to collect the data, they can be described both numerically and verbally. Descriptions usually include measures of central tendency (mean, median, or mode) and dispersion (range, standard deviation).

Qualitative Nursing Research

Qualitative nursing research poses questions about nursing phenomena that cannot be quantified and measured. To answer questions about these phenomena, researchers must understand the perspective of the person in the situation. Researchers using qualitative methods can choose one of many design strategies. Examples of three qualitative designs (ethnography, phenomenology, and grounded theory) are discussed in the following sections, but keep in mind that many other qualitative approaches, such as participatory action research, interpretive descriptive research, and narrative inquiry, are used in nursing research. As with scientific research, the research question is the basis for the choice of design. In addition, each of the various qualitative methods has its own unique underlying philosophy. Ethnography is chosen if the research question leads to the study of behaviour within a specific group or culture, phenomenology if the question relates to the lived experience of the participants, and grounded theory if the question is about a social process.

Ethnography. Ethnography involves the observation and description of behaviour in social settings and is derived from anthropology, where it provides the means to study the culture of groups of people. Anthropologists use participant observation as the major source of data collection, together with other sources such as artifacts and photographs. Nurse

researchers use ethnography to study the behaviour of nurses and their patients in a variety of settings. The goal of ethnography is to understand the culture of the study population as the culture is practised in its own setting. The focus is on the cultural norms and social forces that shape behaviour in a given setting. The researcher becomes an accepted member of the community under study and collects data through repeated interviews of informants from the community. Data collection continues until understanding has been reached about why the members of the community behave as they do. Interview data are supplemented by other forms, such as artifacts and historical documents; the result is a detailed description of the culture. For example, Lauzon Clabo (2008) examined nursing pain assessment practice across two units, to seek variation that might exist and to examine the impact of the social context on pain assessment practice. The ethnographic analysis revealed a predominant pattern of pain assessment on each unit that was profoundly shaped by the social context of the unit.

Phenomenology. The focus of **phenomenology** is on the lived experience of a specific phenomenon from the perspective of the people who are in the situation. Phenomenology has its roots in German philosophy of the early twentieth century, stemming from the philosopher Edmund Husserl (1931–1962), who posited that only people who experience phenomena are capable of communicating these experiences. The researcher must learn to understand a phenomenon from the viewpoint

of people experiencing it. For example, an investigator may want to study the impact of surrogate decision making regarding end-of-life decisions (Weigand, 2008). The goal of this research is to describe fully the lived experience of family when life support is withdrawn. This included their experience in making the decision and the meaning of the decision to withdraw life support. The source of the data is the subject, and the data are the result of in-depth conversations. The units of analysis are the conversations, which are coded and analyzed to extract the meaning to the subjects of the phenomenon.

Grounded Theory. Grounded theory as a research method was developed by Glaser and Strauss (1967) as a means of generating hypotheses and theories about social processes inductively from the data. The grounded theory is “discovered,” developed, and verified through a rigorous process of data collection and analysis. Glaser and Strauss advocated that researchers not review the literature before carrying out the study because they might be influenced by what others have found. The strength of the grounded theory approach comes from examining the situation afresh and opening up the possibility of a new perspective on an old problem.

For example, Duggleby et al. (2009) studied the hope experience of family caregivers of persons with dementia using grounded theory (Box 6-5). The social process was identified as “renewing everyday hope” stemming from the continuous loss and threats to their hope on a daily basis and their choice

* BOX 6-5 RESEARCH HIGHLIGHT

Renewing Everyday Hope: The Hope Experience of Family Caregivers of Persons With Dementia

Research Focus

The study (Duggleby et al., 2009) was carried out by a multidisciplinary team of researchers to explore the hope experience of family members caring for a person with dementia.

Research Abstract

The purpose of this grounded theory study was to explore the experience of hope for family members caring for a person with dementia. Little was known about the topic as only one study had been previously published about hope with this population. The research question was: What is the hope experience of family members caring for a person with dementia? The specific aims were to explore the experience and processes of hope and construct a tentative, emerging theory of the hope experience of family members caring for persons with dementia. This study was approved by a Research Ethics Board of the University of Saskatchewan and the Sunrise Health Region.

The study was conducted in the homes of family members caring for a person with dementia. Participants were eligible to be in the study if they were (a) men or women, (b) 18 years of age or older, (c) the primary caregivers of a person diagnosed with dementia who were receiving home services and long-term care services in a Canadian western health region, and (d) English speaking. A purposive and theoretical sampling approach was used to reach saturation (the data were rich and there were no new ideas arising from the data).

Seventeen family members caring for persons with dementia were interviewed twice using open-ended questions, followed by questions adapted to the individual responses. The trained research data collector

used an interview guide. This guide included questions such as (a) Tell me about hope. (b) What gives you hope? (c) What kinds of things change (increase or decrease) your hope? and (d) What can others do to help you have hope? Interviews lasted 45 to 60 minutes and were audiotaped, after which they were transcribed verbatim. Data were analyzed as they were collected.

The findings suggested that the participants described their hope as the possibility of a positive future within their daily lives. Hope was experienced in the context of grief and loss, stress, fatigue, and constantly dealing with challenging behaviours of the person with dementia. The participants' main concern was “fading hope,” which they dealt with by “renewing everyday hope.” The process of “renewing everyday hope” was achieved through (a) coming to terms with their situation, (b) connecting with others, (c) finding positives, (d) seeing possibilities, and (e) making choices.

The findings reflected the importance of hope in the participants' lives to help deal with their caregiving experience. They described how every day they physically and mentally lean on their hope. Those whose hope was fading may need the support of health care providers to renew their hope.

Implications for Practice

- The findings suggest that hope should be assessed by health care providers.
- Fostering hope may be an important part of supporting family caregivers.
- The emerging theory through its subprocesses suggests several ways to assist caregivers to foster hope, such as weighing positive and negatives, connecting with others, setting goals, and making choices.

to renew their hope. They described almost physically leaning on their hope every day to continue caring for their relative with dementia.

Conducting Nursing Research

Nurses conduct research in a variety of settings. Student nurses and practitioners participate in investigations of patient outcomes and nursing care, commonly called *quality assurance* or *improvement studies*. Data are collected to determine the influence of nurses on achievement of patient care objectives in a particular clinical setting. Because the results usually apply only to one facility, this research is not scientific. However, it is important to the facility involved because the study can demonstrate the contributions made by nurses to patient care and the facility can improve processes if necessary.

Clinical nursing research should be undertaken by nurses educated to conduct scientific investigations (Figure 6-2). An experienced researcher is usually more qualified than a beginner to undertake a complex, long-term project. Nurses new to research may, however, assist with data collection, conduct replication studies (studies previously performed elsewhere), or conduct less complex studies.

Ethical Issues in Research

Research must meet ethical standards in ways that respect the dignity and preserve the well-being of human research participants. In Canada, every health care facility and university receiving public funds for research must meet federal standards for protecting human research participants. The most recent standard is the *Tri-Council Policy Statement* (Canadian Institutes of Health Research et al., 2010), which requires that the institution have in place a research ethics board (REB) to review all research proposals to determine whether ethical principles are being upheld (Box 6-6). The REB focuses on **informed consent** and weighs benefits versus harms from the research. No research may be performed in a university or health care facility without the approval of the REB. All proposals are subject to review. However, if data collection processes (such as quality assurance studies) are a normal part of institutional business, performance reviews, or testing within normal educational requirements and are not for research purposes, they are exempt from REB review.

► BOX 6-6

Guiding Ethical Principles for Research in Canada

1. *Respect for human dignity:* All research must be conducted in a manner that is sensitive to the inherent worth of human beings.
2. *Respect for persons:* Includes the obligation to respect autonomy of human research subjects and at the same time to protect those with developing, impaired, or diminished autonomy.
3. *Concern for welfare:* Researchers and Ethics Review Boards should aim to protect the welfare of participants and when possible promote their welfare.
4. *Respect for privacy and confidentiality:* Standards of privacy and confidentiality protect the access, control, and dissemination of personal information and thus help protect mental or psychological integrity. These standards are consonant with values underlying privacy, confidentiality, and anonymity.
5. *Justice:* This principle reflects the importance of treating people fairly and equitably. This treatment includes ensuring that research participants are not unduly burdened by research or denied access to the benefits of research.

Adapted from Canadian Institutes of Health Research, the Natural Sciences and Engineering Research Council of Canada, & the Social Sciences and Humanities Research Council of Canada. (2010). *Tri-Council policy statement: Ethical conduct for research involving humans* (2nd ed.). Retrieved from http://pre.ethics.gc.ca/pdf/eng/tcps2/TCP2_FINAL_Web.pdf.

To refine existing knowledge and develop new knowledge, investigators in clinical research sometimes use new procedures whose outcome is doubtful or unknown. This research may seem to conflict with the purpose of nursing practice, which is to meet specific patients' needs. In such cases, the investigator must structure the research to avoid or minimize harm to the subjects. Although not all undesirable effects can be anticipated, investigators are obligated to inform everyone involved about the known potential risks. Other basic human rights must also be observed. These principles are set forth by the CNA (2008). Procedures for obtaining informed consent must be outlined in the study protocol. The consent form must describe in lay language the purpose of the study, the role of the subjects, types of data that are to be obtained, how the data are obtained, the duration of the study, subject selection, procedures, risks to the subject (including financial risks), potential benefits (including the possibility of no benefit), alternatives to participation, and contact information concerning the principal investigator and local REB. The consent process gives subjects complete information regarding the study's risks, benefits, and costs so that they can make an informed decision.

The REB also determines whether the investigator has the necessary knowledge and skills to undertake the research, including familiarity with the clinical area in which the data will be collected and sufficient research training and experience. For example, a nurse planning a study of psychiatric patients should be familiar with psychiatric nursing principles and theory, as well as research procedures for data collection and analysis.

Rights of Other Research Participants

Student nurses and practising nurses may be asked to participate in research as data collectors or may be involved in the care of patients participating in a study. All participants, including health care providers, have the right to be fully

informed about the study, its procedures (including the consent process and risk factors), and physical or emotional injuries that patients could experience as a result of participation. Often, the physical risks are more obvious than the emotional risks. For example, patients may be asked to give highly personal, intrusive information; some may find this experience stressful. The researcher should prepare all participants, including nurses delivering care, for this possibility and assist them in coping with the effects. Participants also have the right to see review forms from the REB that certify approval of the study. Participants can refuse to perform research procedures if they are concerned about ethical aspects.

Applying Research Findings to Nursing Practice

Research evidence as a basis for scholarly, professional decision making in clinical practice is essential for providing competent, efficient, and state-of-the-art nursing care (Brown et al., 2009). Advances in care through research are meaningless unless they are accessible to nurses at the point of care. You make links between research findings and nursing care by reading relevant literature, identifying appropriate clinical problems, and incorporating evidence-informed practice activities into the nursing practice of your nursing unit or agency.

In a policy statement, the CNA (2010) stated that evidence-informed decision making by registered nurses is key to quality nursing practice. Nurses need not only skills to access and appraise existing research but also scientific knowledge and skills to change practice settings and to promote evidence-informed decisions about patient care.

Evidence-informed nursing practice deemphasizes ritual, isolated, and unsystematic clinical experiences; ungrounded opinion; and tradition as bases for nursing practice. It stresses the use of research findings and, as appropriate, quality improvement data, other evaluation data, and the consensus of recognized experts and affirmed experience to support a specific practice (Cleary-Holdforth, 2009). Many aspects of health care are not justly served by the research in only one discipline. The expertise of several disciplines must be brought to bear on complex health issues. Just as nurses play a vital role on the health care team, so they are crucial to multidisciplinary health research. Policymakers in the broader arena of health care must account for nursing practice, which is so essential to patient care. Nurses need a sound knowledge base to support practice, and research is essential for building that knowledge.

❖ KEY CONCEPTS

- Nursing knowledge has five patterns: empirics, esthetics, personal knowledge, ethics, and emancipatory knowledge.
- A scientific investigation is an orderly, planned, and controlled study of real-life situations that tests theories and whose results can be applied to general situations.
- In nursing research, physical or psychosocial responses of people of all ages in various states of health and illness are examined.
- In an experimental research study, investigators control factors that could influence the results, include comparison and experimental treatment groups of subjects, and use random means for selecting study subjects.
- In a qualitative research study, investigators organize information in narrative format so that phenomena can be described and patterns of relationships can be discovered.

- When human subjects participate in research, the researcher must obtain informed consent of study subjects, must maintain the confidentiality of subjects, and must protect subjects from undue risk or injury.
- When summarizing data reported in a research study, the nurse should note when, how, where, and by whom the investigation was conducted and who and what were studied.
- A researchable clinical nursing problem is one that is not satisfactorily resolved by current nursing interventions, occurs frequently in a particular group, can be measured or observed, and has a possible solution within the realm of nursing practice.
- To determine whether research findings can be used in nursing practice, the nurse considers the scientific worth of the study by substantiating evidence from other studies, the similarity of the research setting to the nurse's own clinical practice setting, the status of current nursing theory, and factors affecting the feasibility of application.

❖ CRITICAL THINKING EXERCISES

1. The nurse is concerned about learning to properly treat a pressure ulcer. Explain the benefits to the patient if the nurse learns how to treat the sore by drawing from information in the research literature rather than using the scientific method.
2. The research literature reflects many different methods for treating pressure ulcers. If you wished to determine the best method for doing this, what type of research design would you use?
3. The nurses working on an orthopedic unit decide to study the factors that commonly result in patients' falling in their unit. How could they design a study to answer their questions?

❖ REVIEW QUESTIONS

1. The first provincially approved doctoral program in nursing was established in
 1. 1969
 2. 1974
 3. 1982
 4. 1991
2. Empirics is described by Carper (1978) as
 1. The artistic expression of knowledge
 2. Knowledge derived from the interpersonal relationship with the patient
 3. Knowledge derived from ethical dilemmas
 4. Knowledge systematically organized into general laws and theories
3. The quantitative research approach is characterized by
 1. Systematic procedures that seek to limit error and eliminate bias
 2. Studies of behaviours, experiences, perceptions, and motives
 3. A commitment to the participants' point of view
 4. The use of the participants' natural setting
4. If the research question leads to the study of behaviour within a specific culture, the design chosen is
 1. Phenomenology
 2. Grounded theory
 3. Ethnography
 4. Quantitative research

5. Subjectivity is the goal of
 1. Positivism
 2. Qualitative research
 3. True experiments
 4. Quantitative research
6. Which research method is quantitative?
 1. Grounded theory
 2. Phenomenology
 3. Ethnography
 4. Quasi-experimental research
7. A sample in a survey design
 1. Is the main component of qualitative research
 2. Should be representative of the population surveyed
 3. Should be small enough to keep sampling error to a minimum
 4. Should be no different from the control group
8. Procedures for obtaining informed consent do *not* include
 1. Describing the purpose of the study
 2. Describing the role of the subjects
 3. Giving the names of other participants in the study
 4. Describing the risks that the subject may incur
9. In a quasi-experimental research design, subjects are assigned to
 1. An empirical group
 2. An ethnographic group
 3. Either a control group or a treatment condition, but not randomly
 4. An experimental group

10. Evidence-informed practice
 1. Enables the transfer of clinical practice techniques into a positivist paradigm
 2. Requires that evidence be always research based
 3. Is synonymous with research-based practice
 4. Entails the use of knowledge based on research studies and takes into account a nurse's clinical experience and patient preferences

Nursing Values and Ethics

Canadian content written by Shelley Raffin Bouchal, RN, PhD

Based on original chapter by Margaret Ecker, RN, MS

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss the role of values in the study of ethics.
- Examine and clarify personal values.
- Discuss how values influence patient care.
- Explain the relationship between ethics and professional nursing practice.
- Describe some basic ethical philosophies relevant to health care.
- Apply a method of ethical analysis to a clinical situation.
- Identify contemporary ethical issues in nursing practice.

Values and ethics are inherent in all nursing acts. A **value** is a strong personal belief and an ideal that a person or group (such as nurses) believe to have merit. **Ethics** is the study of the philosophical ideals of right and wrong behaviour based on what you think you ought (or ought not) to do. The term also commonly refers to the values and standards that individuals and professions strive to uphold (e.g., health care ethics, nursing ethics). In other words, ethics are a reflection of what matters most to people or professions. Nurses and other health care providers agree to national codes of ethics that offer guidelines for responding to difficult situations that occur in practice and demonstrate to the public an overview of professional practice standards. For example, the Canadian Nurses Association (CNA, 2008) publishes a **code of ethics** that outlines nurses' professional values and ethical commitments to their patients and the communities they serve.

Because of their prominent and intimate role in the provision of health care, nurses continually make decisions about the correct course of action in different circumstances. In many situations, no answer or course of action is best. To manage such difficult situations, nurses need a keen awareness of their values and those of their patients, a good understanding of ethics, and a sound approach to ethical decision making. They also must be guided by a broader understanding of ethics through the application of philosophies, theories, and sets of principles.

Values

Values are at the heart of ethics. Values influence behaviour on the basis of the conviction that a certain action is correct in a certain situation. An individual's values reflect cultural and social influences, relationships, and personal needs. Values vary among people, and they develop and change over time. In the context of beliefs about morality, values generate rights and duties.

In nursing, value statements express broad ideals of nursing care and establish reasonable directions for practice. The CNA (2008, pp. 8–18) *Code of Ethics for Registered Nurses* is organized around seven values that are central to ethical nursing practice. These values include providing safe, compassionate, competent, and ethical care; promoting health and well-being; promoting and respecting informed decision making; preserving dignity; maintaining privacy and confidentiality; promoting justice; and being accountable. Each provincial nursing association also has shared values, such as those held in position statements and practice standards. These standards reflect the values of the profession and clarify what is expected of you as a practising nurse.

Because of the intimacy of the nurse–patient relationship, you must be aware of your personal values, as well as the values of patients, physicians, employers, or other groups. To understand the values of others, it is important to understand your own values: what they are, where they came from, and how they relate to others' values.

Values Formation

People acquire values in many ways, beginning in early childhood. Throughout childhood and adolescence, people learn to distinguish right from wrong and to form values on which to base their actions. This is known as *moral development* (see Chapter 22). Family experiences strongly influence value formation.

Values are also learned outside the family. A person's culture, ethnic background, and religious community strongly influence that person's values, as do schools, peer groups, social media, and work environments. **Cultural values** are those adopted as a result of a social setting (see Chapter 9). A basic task of the young adult is to identify personal values within the context of the community. Over time, the person acquires values by choosing some values that are strongly upheld in the community and by discarding or transforming others. A person's experience as well as lack of experience also influences his or her values.

Values Clarification

Within the context of nursing, several layers of values inform the ethical questions and actions that you consider in your practice. Clarifying your values helps you articulate what

► BOX 7-1 Values Clarification Questions

Describe a situation in your personal or professional experience in which you felt uncomfortable, in which you believed that your beliefs and values were being challenged, or in which you believed your values were different from others'.

- As you record the situation, mention how you felt physically and emotionally at the time you experienced the situation.
- Write down your feelings as you remember the situation. Are your current reactions any different from those when you were actually in the situation?
- What personal values do you identify in the situation? Try to remember where and from whom you learned these values. Do you completely agree with the values, or do you question some aspect of the values, or do you wonder about their validity?
- What values do you think were being expressed by others involved? Are they similar to or different from your own values?
- What do you think you reacted to in the situation?
- Can you remember having similar reactions in other situations? If you do, how were the situations similar or different?
- How do you feel about your response to the situation? If you could repeat the scenario, would you change something about it? Rewrite the scenario with the same changes. What might be the consequences of these same changes?
- How do you feel about the new scenario?
- What do you need to do to reinforce behaviours, ideals, beliefs, and qualities that you have identified as personal values in this situation? When and how can you do this?

From Burkhardt, M. A., & Nathaniel, A. K. (2007). *Ethics and issues in contemporary nursing* (3rd ed.). Albany, NY: Thomson Delmar Learning. Copyright © Delmar, a part of Cengage Learning, Inc. Reproduced by permission (www.cengage.com/permissions).

matters most and what priorities are guiding your life and decision making. Values influence how you interpret confusing or conflicting information. Values change as you mature and experience new situations. As you become more aware and reflective about who you are, you may consider embracing or modifying your value set. As a result, you may modify your attitudes and behaviour. The willingness to change reflects a healthy attitude and an ability to adapt to new experiences.

To adopt new values, you must be aware of your existing values and how they affect behaviour. **Values clarification** is the process of appraising personal values (Box 7-1). It is not a set of rules, nor does it suggest that certain values should be accepted by all people; rather, it is a process of personal reflection. When you clarify your values, you make careful choices. The result of values clarification is greater self-awareness and personal insight.

By understanding your personal values, you will become more sensitive to the values of others. In *value conflict*, personal values are at odds with those of a patient, a colleague, or an institution. Values clarification plays a major role in resolving these dilemmas. In addition, you can better advocate for a patient when you can identify your personal values and the values of the patient.

Enhancing your skill of values clarification opens possibilities to help patients identify their personal priorities, values, and emotions. This may help patients resolve conflicts between values and behaviours. The goal of values clarification with patients is for honest and open dialogue. As the patient becomes more willing to express concerns and feelings, you

can collaborate with the patient in developing an individualized plan of care.

Relational communication is a useful way in which to clarify values with a patient. Strategies that promote the process of connecting can be effective. For example, responding to a patient by repeating the patient's sentence as a question ("You wish you could be at home?") encourages the patient to continue the story. Instead of asking questions that can be answered by only yes or no, you can encourage the patient to answer in greater detail. For example, rather than asking, "Do you want to live at home with your daughter?" the nurse might say, "Tell me how you feel about living at home with your daughter."

Relational communication can encourage the patient to examine personal thoughts and actions. When you make a clarifying response, it should be brief and nonjudgemental. For example, when talking with a patient who exercises only rarely, you might ask, "What is your understanding of the purpose of exercise?" A supportive clarifying response encourages the patient to think about personal values after the exchange is over and does not impose your own values onto the patient. In this way, you respect the patient's values and avoid inappropriately introducing personal values into the conversation.

Values clarification plays a key role in communication. In particular, when the topic concerns issues of personal health, private habits, and quality of life, participants in a discussion benefit from clarity of values. In appreciating values, you can identify differences between personal opinion and the values that others embrace. Through values clarification, you can better serve the needs of patients, especially when values differ. By demonstrating respect for the patient's differences and helping the patient to clarify values, you are practising responsibly and ethically.

Ethics

Ethics is the study of good conduct, character, and motives. It is concerned with determining what is good or valuable for all people. Often the terms *ethics* and *morals*, or *morality*, are used interchangeably (Johnstone, 2009), inasmuch as both words are derived from an original meaning of "custom or habit." Johnstone suggested that it is not incorrect to use these terms interchangeably and that the choice is a matter of personal preference rather than of philosophical debate. The classic textbook definition of *ethics* is a "generic term for various ways of understanding and examining the moral life" (Beauchamp & Childress, 2009, p. 1). Essentially, ethics requires you to be critically reflective, exploring your values, behaviours, actions, judgements, and justifications (Beauchamp & Childress, 2009, p. xii). In this chapter, the terms *ethics* and *morals* are used interchangeably.

Nursing and Ethics

Codes of Ethics. A "code of ethics serves as a foundation for nurses' ethical practice" (CNA, 2008, p. 3) and is accepted by all members of a profession. The code is a statement of the ethical values of nurses and of nurses' commitments to patients with health care needs and patients who receive care. It is intended for nurses in all contexts and domains of practice (individuals, families, communities, and public health care systems) and at all levels of decision making. The code developed by nurses for nurses serves the profession

when questions arise about practising ethically and working through ethical challenges (CNA, 2008). The code embodies the collective wisdom of our profession, institution, or community. The nursing code of ethics, as in other professions, sets forth ideals of conduct.

"The code provides guidance for ethical relationships, responsibilities, behaviours and decision-making and it is to be used in conjunction with professional standards, laws, and regulations that guide practice" (CNA, 2008, p. 4). It does not provide rules of behaviour for every circumstance. Situations are unique to the context in which they occur. The environment or institution can greatly influence the values that you are encouraged to uphold. Furthermore, a code does not offer guidance as to which values should take priority or how to balance them in practice.

The CNA and the International Council of Nurses (2006) have established widely accepted codes for nurses that reflect the principles of responsibility, accountability, and advocacy (Boxes 7-2 and 7-3).

Responsibility. Responsibility refers to the characteristics of reliability and dependability. It implies an ability to distinguish between right and wrong. In professional nursing, responsibility includes a duty to perform actions adequately and thoughtfully. When administering a medication, for example, you are responsible for assessing the patient's need for the drug, for administering it safely and correctly, and for evaluating the patient's response to it. By agreeing to act responsibly, you gain trust from patients, colleagues, and society.

► BOX 7-2

Canadian Nurses Association Code of Ethics

The following is the CNA's statement of the seven values that must be upheld in nursing practice. The complete code of ethics also includes responsibility statements outlining how nurses can incorporate these values into their practice; it can be found on the CNA Web site (see the "Recommended Web Sites" section at the end of this chapter).

Providing Safe, Compassionate, Competent, and Ethical Care

Nurses provide safe, compassionate, competent, and ethical care.

Promoting Health and Well-Being

Nurses work with patients to enable them to attain their highest level of health and well-being.

Promoting and Respecting Informed Decision Making

Nurses recognize, respect, and promote a patient's right to be informed and make decisions.

Preserving Dignity

Nurses recognize and respect the intrinsic worth of each patient.

Maintaining Privacy and Confidentiality

Nurses recognize the importance of privacy and confidentiality, and they safeguard personal, family, and community information obtained in the context of a professional relationship.

Promoting Justice

Nurses uphold principles of justice by safeguarding human rights, equity, and fairness in promoting the public good.

Being Accountable

Nurses are accountable for their actions and answerable for their practice.

Adapted from Canadian Nurses Association. (2008). *Code of ethics for registered nurses*. Ottawa: Author.

► BOX 7-3

International Council of Nurses: The Code of Ethics for Nurses

Nurses have four fundamental responsibilities: to promote health, to prevent illness, to restore health, and to alleviate suffering. The need for nursing care is universal. Inherent in nursing care is respect for human rights, including cultural rights, the right to life and choice, the right to dignity, and the right to be treated with respect. Nursing care is respectful of and unrestricted by considerations of age, creed, culture, disability or illness, gender, sexual orientation, nationality, politics, race, economic status, or social status. Nurses render health services to the individual, the family, and the community, and they coordinate their services with those of related groups.

Nurses and People

The nurse's primary professional responsibility is to patients who require nursing care. In providing care, the nurse promotes an environment in which the human rights, values, customs, and spiritual beliefs of the individual patient, family, and community are respected. The nurse ensures that the individual patient receives sufficient information on which to base consent for care and related treatment. The nurse keeps the patient's personal information confidential, sharing it only with appropriate other professionals. The nurse shares with society the responsibility for initiating and supporting action to meet the health and social needs of the public, particularly those of vulnerable populations. The nurse also shares responsibility to sustain and protect the natural environment from depletion, pollution, degradation, and destruction.

Nurses and Nursing Practice

The nurse carries personal responsibility and accountability for nursing practice and for maintaining competence by continual learning. The nurse maintains a standard of personal health in such a way that the ability to provide care is not compromised. The nurse uses judgement regarding individual competence when accepting and delegating responsibility. The nurse at all times maintains standards of personal conduct that reflect positively on the profession and enhance public confidence. In providing care, the nurse ensures that the use of technology and scientific advances is compatible with the safety, dignity, and rights of patients.

Nurses and the Nursing Profession

The nurse assumes the major role in determining and implementing acceptable standards of critical nursing practice, management, research, and education. The nurse is active in developing a core of research-based professional knowledge. The nurse, acting through the professional organization, participates in creating and maintaining equitable social and economic working conditions in nursing.

Nurses and Co-workers

The nurse sustains a cooperative relationship with co-workers in nursing and other fields. The nurse takes appropriate action to safeguard patients when their care is endangered by a co-worker of the nurse or by any other person.

Adapted from International Council of Nurses. (2006). *ICN code of ethics for nurses*. Geneva, Switzerland: Author. Reprinted by permission of International Council of Nurses.

Nurses in all domains of practice uphold responsibilities related to all the values in the code of ethics. You are responsible in your interactions with individual patients, families, groups, populations, communities, and society, as well as with students, nursing colleagues, and other health care colleagues.

These responsibilities serve as the foundation for articulating nursing values to employers, other health care providers, and the public (CNA, 2008).

Accountability. Accountability is grounded in the moral principles of fidelity (faithfulness) and respect for the dignity, worth, and self-determination of patients and others with whom nurses work. As accountable professionals, "nurses are honest and practice with integrity in all of their professional interactions" (CNA, 2008, p. 18). **Accountability** means being able to accept responsibility or to account for one's actions and refers to being answerable to someone for something one has done. **Answerability** means being able to offer reasons and explanations to other people for aspects of nursing practice. When explanations are not readily available to patients, you might seek advice of other health care providers or search for evidence that would support best practice. You balance accountability to the patient, the profession, the employer, and society. For example, you may know that a patient who will be discharged soon is confused about how to self-administer insulin. The action that you take in response to this situation is guided by your sense of accountability. The patient, the institution, and society rely on your judgement and trust you to take action in response to this situation. You may request more hospitalization to provide further teaching, or you may arrange home care to continue teaching at home. The goal is the prevention of injury to the patient. Your sense of accountability guides actions that achieve this goal.

According to the CNA (2008), nurses who are enacting professional accountability are (1) keeping up with professional standards, laws, and regulations; (2) ensuring that they have the skill to provide these practices; (3) maintaining their fitness to practise, ensuring that they have the necessary physical, mental, and emotional capacity to practise safely and competently; and (4) sharing their knowledge with other nurses through mentorship and giving feedback to other nurses when appropriate.

Professional accountability is also the mandate of professional associations. Professional associations both check unethical practice in a profession and support conscientious professionals who may be under pressure to act unethically or to overlook unethical activity by colleagues. Professional nursing associations have the authority to register and discipline nurses. They also set and maintain professional standards of practice and communicate them to the public. These standards, developed by nursing clinical experts, provide a basic structure against which nursing care is objectively measured.

Advocacy. The ethical responsibility of **advocacy** means acting on behalf of another person, speaking for persons who cannot speak for themselves, or intervening to ensure that views are heard. The CNA (2008) advises nurses to advocate for all patients in their care. This includes protecting the patient's right to choice by providing information, obtaining informed consent for all nursing care, and respecting patients' decisions. Nurses should protect patients' right to dignity by advocating for appropriate use of interventions in order to minimize suffering, intervening if other people fail to respect the dignity of the patient, and working to promote health and social conditions that allow patients to live and die with dignity. Nurses should protect a patient's right to privacy and confidentiality by helping the patient access his or her health records (subject to legal requirements), intervening if other members of the health care team fail to respect the patient's

privacy, and following policies that protect the patient's privacy. According to the *Code of Ethics*, nurses should also advocate for the discussion of ethical issues among health care team members, patients, and families, and nurses should advocate for health policies that enable fair and inclusive allocation of resources.

Advocacy requires that you have a strong awareness of the context in which situations arise, as well as an understanding of the influence of power and politics on how you make decisions. If you experience **constrained moral agency**—that is, if you feel powerless to act for what you think is right, or if you believe your actions will not effect change—then you will have difficulty being an effective advocate.

Ethical Theory

Ethics concern the examination of the moral basis for judgments, actions, duties, and obligations. For centuries, moral philosophers have tried to answer perplexing questions that help us understand the world. They structure this understanding in the form of philosophical theories. Different branches of philosophy answer different questions you are grappling with. The field of ethics, also called moral philosophy, addresses questions like “What is the meaning of right and good, or ought and should?” **Descriptive moral theory** explains what people do or think about moral issues. For example, a descriptive theory might emerge from studies of how nurses make moral decisions. Such theory describes the rules, principles, and values that people apply when making moral decisions or judgments in different situations. Taking this one step further, philosophers ask, “Do we believe this is the right way to make moral decisions, just because many people do it this way?” Answering that question requires an understanding of what the “right” way would be. This understanding is called **metaethics**. A person studying metaethics might ask if “good” is socially related, an expression of emotion, or the will of a higher power, such as God. Is “good” out there to be discovered, or is it really socially constructed? Is there a true “right,” and on what moral basis can moral judgments be assessed as being true or false?

Another branch of moral philosophy is **normative ethics**. A normative ethical theory is prescriptive, in that it tells us how we ought to think about moral questions. Normative ethical theory presents us with rules, values, and principles that allow us to judge the quality and the way we make and evaluate decisions, based on our obligations to others. Normative theories question or reveal our obligations as nurses. These are clearly stated in the *Code of Ethics for Registered Nurses*.

Applied ethics (or practical ethics) looks at how decisions should be made in particular situations, asking questions about what moral belief and values should apply in specific contexts. Theories that address issues of right or ought in applied ethics move across disciplines. Applied ethics specific to nursing helps us to examine our practice and how our behaviours are shaped by our practice as nurses. A nurse might reflect on how medical technology changes the way she communicates with family regarding nutrition at the end of life. The following section introduces a variety of contemporary ethical theories. It is neither exclusive nor comprehensive.

Deontology. A traditional ethical theory, **deontology** is the system of ethics that is perhaps most familiar to practitioners in health care. Its foundations are often associated with the work of the eighteenth-century philosopher Immanuel

Kant (1724–1804). In deontology, actions are defined as right or wrong on the basis of their right-making characteristics such as fidelity to promises, truthfulness, and justice (Beauchamp & Childress, 2009). The essence of right or wrong is located within deontological principles. Deontologists specifically do not look to consequences of actions to determine rightness or wrongness. Instead, they critically examine a situation for the existence of essential rightness or wrongness. Ethical principles such as justice, allowing free choice (autonomy), and doing the greatest good (beneficence) serve to define right or wrong. If an act is just, respects autonomy, and provides good, then the act is ethical. The process depends on a mutual understanding and acceptance of these principles.

Difficulty arises when you must choose among conflicting principles, which is often the case in ethical dilemmas concerning health care. For example, applying the principle of respect for autonomy can be confusing when dealing with the health care of children. The health care team may recommend a treatment, but a parent may disagree with or refuse the recommendation. In discussion of the dilemma, you may refer to a guiding principle such as respect for autonomy. However, questions remain: Whose autonomy should receive the respect? That of the parents? Who should advocate for the child's best interest? Society often struggles to understand who should be ultimately responsible for the well-being of children. A commitment to respect autonomy does not guarantee that controversy can be avoided.

Utilitarianism. According to a utilitarian system of ethics, the value of something is determined by its usefulness. This philosophy, **utilitarianism**, may also be known as **consequentialism** because its main emphasis is on the outcome or consequence of action. A third term associated with this philosophy is **teleology** (from the Greek word *telos*, meaning “end”), which is the study of ends or final causes. Its philosophical foundations were first proposed by John Stuart Mill (1806–1873), a British philosopher and social commentator. The greatest good for the greatest number of people is the guiding principle for determining the correct action in this system. As with deontology, this theory relies on the application of a certain principle, namely measures of “good” and “greatest” (Beauchamp & Childress, 2009). The difference between utilitarianism and deontology is in the focus on consequences or outcomes. Utilitarianism concerns the effect that an act will have; deontology concerns the presence of principle, regardless of outcome.

Individuals or groups may have conflicting definitions of “greatest good.” For example, research suggests that education regarding safer sex practices may reduce the spread of the human immunodeficiency virus. Some scholars argue, however, that education about sex should be provided by the family and that sex education in public schools diminishes the role and the value of the family. For them, the greater good is the preservation of family values and the protection of individual choices regarding sex education of children. For other scholars, however, the “greater good” is defined as educating the greatest number of people in the most effective way possible. The concepts of utilitarianism provide guidance, but they do not invariably provide for universal agreement.

Bioethics. In the 1970s, a group of ethics scholars concluded that then-current ethical theories were not sufficient for the health care field because they did not provide specific guidance for important moral questions that arose in the context of medicine. **Biomedical ethics** came to denote ethical reasoning

for physicians, whereas **bioethics** became the general term for principled reasoning across health care professions. Bioethical theory is obligation-based, outcome-oriented, and based on reason (Oberle & Raffin Bouchal, 2009). The central idea of bioethics is that moral decision making in health care should be guided by four principles: autonomy, beneficence, nonmaleficence, and justice. According to this theory, health care providers should examine each situation, determine which of the principles has priority, and use that principle to guide action.

Autonomy. **Autonomy** refers to your ability to make choices for yourself that should be based on full understanding, free of controlling influences (Beauchamp & Childress, 2009). Respect for another person's autonomy is fundamental to the practice of health care. It is the reason why patients should be included in all aspects of decision making regarding their care. The agreement to respect autonomy involves the recognition that patients are free to make choices and have the capacity to do so. Health care providers assess patient capacity and help to facilitate decision making. For example, the purpose of the preoperative consent that patients must read and sign before surgery is to ensure in writing that the health care team respects the patient's choice by obtaining permission to proceed. The consent process implies that a patient may refuse treatment, and in most cases, the health care team must agree to follow the patient's wishes. Health care providers agree to abide by a standard of respect for the patient's autonomy, which comes directly from Kant's ethics and his idea of respect for persons.

Beneficence. **Beneficence** means doing or promoting good for others. It speaks directly to the duty or obligation, as in deontological theories. Commitment to beneficence helps guide difficult decisions concerning whether the benefits of a treatment may be challenged by risks to the patient's well-being or dignity. For example, vaccination may cause temporary discomfort, but the benefits of protection from disease, both for the patient and for society, outweigh the patient's discomfort. The agreement to act with beneficence also requires that the best interests of the patient remain more important than self-interest. For example, you do not simply follow medical orders; you act thoughtfully to understand patient needs and then work actively to meet those needs.

Nonmaleficence. **Maleficence** refers to harm or hurt; thus **nonmaleficence** is the avoidance of harm or hurt. The health care provider tries to balance the risks and benefits of a plan of care while striving to cause the least harm possible. This principle is often helpful in guiding discussions about new or controversial technologies. For example, a new bone marrow transplantation procedure may provide a chance for cure. The procedure, however, may entail long periods of pain and suffering. These discomforts should be considered in view of the suffering that the disease itself might cause and in view of the suffering that other treatments might cause. The commitment to provide least harmful interventions illustrates the term *nonmaleficence*. The standard of nonmaleficence promotes a continuing effort to consider the potential for harm even when it may be necessary to promote health.

Justice. **Justice** refers to fairness. The term is often used during discussions about resources: when competition for a scarce resource exists, justice mandates that decisions be fair and, to the greatest extent possible, unbiased. In decisions about which patient receives an available lung for transplantation, for example, it is understood that the lung will be allocated as fairly as possible. Understandings of fairness depend

on community values. In Canadian society, community standards dictate that the decision should not depend on who has the higher intellect or larger salary; instead, the decision must be based on need alone. Of course, the definition of need can be debated, and when two people have equal need, nothing in the theory helps health care providers decide between them. These are ethical questions that require further exploration of values, principles, and priorities to guide decisions in resource allocation.

The literature also mentions other prevalent forms of justice that you need to understand, such as **social justice**. Social justice is often related to a concern for the equitable distribution of benefits and burdens in society (Boutain, 2005), with the view that broad social change is necessary to address the determinants of health and reduce inequalities of health (World Health Organization, 2008). According to the "Ethical Endeavours" section of the CNA (2008) *Code of Ethics*, your moral obligations extend to recognizing "the need for change in systems and societal structures in order to create greater equity for all. You should endeavour as much as possible, individually and collectively, to advocate for and work toward eliminating social inequities . . ." (p. 16). This section of the *Code of Ethics* is somewhat visionary, inasmuch as its statements extend beyond just "what is" to "what ought to be" in nursing as a profession. It makes clear that if the status quo in health care is inefficacious, you must be an active participant in effecting change. This means you must recognize that part of your role is to work for change at the broader systems level, agitating for revisions to social policy, legislation, and institutional structures. This section of the *Code of Ethics* emphasizes the advocacy role for you and the need to work to bring about a system that is more focused on prevention, takes more account of the social determinants of health, is more accessible, and is more sustainable. Other scholars of bioethics, including Canadians Michael Yeo, Anne Moorhouse, Pamela Kahn, and Patricia Rodney (2010), who have written about nursing ethics, have incorporated a number of other principles such as fidelity (faithfulness), veracity (truth-telling), and confidentiality.

Feminist Ethics. Feminist ethicists consider their work a critique of conventional ethics, as well as a critique of social values. Their work focuses on continuing inequalities between people (Lindemann, 2006). A feminist ethics approach embodies features of being attentive to issues of difference; attentiveness to power dynamics; and being attentive to context and relatedness (Yeo et al., 2010). Feminist ethics is relevant for nurses in the deliberation of ethical issues as an expressive and collaborative process. Nurses hear the stories of patients and consider their social context in making ethical decisions.

Changes in attitudes toward women reflect new perspectives in women's relationship with family, with work, with science, and with society (Sherwin, 1992). For example, until the early 1980s, moral development was thought to reach the highest stages more often in men than in women. According to this thinking, moral development occurred in predictable stages. The most complex stage involved a sense of justice, and young girls did not reach this stage as often as did young boys (Kohlberg, 1981). Findings of research in the early 1980s disputed this conclusion. Gilligan (1982) proposed that Kohlberg's tools to measure moral development were gender biased. Gilligan went on to build a revised theory of moral development from her findings. She attempted to accommodate gender differences. Specifically, she concluded that young

girls tend to pay attention to community and to individual circumstances and that young boys tend to process dilemmas through ideals or principles determined abstractly.

Feminism proposes that gender makes a difference in the construction of roles and identities in society, and accordingly in how individuals and groups are treated. Feminist ethics holds the belief that society remains “patriarchal” in many ways (Yeo et al., 2010). Hilde Lindemann Nelson (2000), a noted feminist scholar in the United States, provided a history of the development of feminist ethics and bioethics. She noted that the feminist attention to gender and gender-related issues gave rise to an important perspective called **care theory**, which is about a type of virtue ethic that gives moral weight to caring for others (see Chapter 18). This was an important development in thinking about ethics because it moved attention away from the traditional masculine virtues toward those that had traditionally been considered more feminine.

Relational Ethics. It is becoming increasingly apparent that relationships are the basis of ethics in nursing. According to **relational ethics** theory, ethical understandings are formed in, and emerge from, a person’s relationships with others, whether those others are patients, families, communities, or colleagues (Bergum, 2004; Bergum & Dossetor, 2005; Hartrick Doane & Varcoe, 2007; Wright & Brajtman, 2011). According to Bergum (2004), relational ethics is a way of “being,” displayed in everyday interactions rather than a mode of decision making. It is how you insert a needle, how you enter into conversation, how you show respect, or how you behave with other people.

Relational ethics focuses on the role of relational context or the experience of the relationships in shaping moral choices (Bergum, 2004; Wright & Brajtman, 2011). In research on relational ethics, Bergum (2004) identified four themes: environment, embodiment, mutual respect, and engagement. **Environment** concerns critical elements or characteristics of the health care system within which you work and how the nature of your relationships is affected by this system. Bergum encouraged nurses to consider the entire health care arena as a network or matrix, in which each part is connected, either directly or indirectly, to the other. An awareness of this connectedness encourages you to look beyond the immediate situation and try to envision a broader context. It also makes you conscious of how power and politics affect your entire system of care (Oberle & Raffin Bouchal, 2009).

In relational ethics, **embodiment** means recognizing that the mind–body split is artificial and that healing for both patient and family cannot occur unless “scientific knowledge and human compassion are given equal weight [and it is recognized that] emotion and feeling are as important to human life as physical signs and symptoms” (Bergum, 2004, p. 492). Such recognition requires you to become truly aware of what other people may be experiencing. You must make this awareness a part of your own experience. The nurse–patient relationship requires that you value patients and treat them with respect. Within the nurse–patient relationship, you use nursing knowledge to enhance the patient’s health and well-being. You always consider the unique needs of the patient as an individual. Mutual respect is created, with attention to both your and the patient’s needs, wishes, expertise, and experience (Bergum & Dossetor, 2005). **Mutuality**, loosely defined as a relationship that benefits both you and the patient and harms neither, requires your and the patient’s willingness to participate in a relationship that embraces the

values and ideas of one another as a means of developing new understandings, rather than judging the other person’s values and ideas.

Engagement means connecting with another person in an open, trusting, and responsive manner. Bergum (2004) suggested that it is through this connection that you develop a meaningful understanding of the other person’s experience. Engagement takes skill and practice, inasmuch as it requires a commitment to keeping the relationship caring and respectful. Bergum asserted that engagement “does not ask for *selflessness* on the part of you, but for both you and the patient to be recognized as *whole beings*” (p. 498). Engagement requires that you connect with the patient but, at the same time, set boundaries in such a way that the relationship remains on a professional level. Knowing how much to engage with another person is one of the greatest challenges in nursing.

Ethical Analysis and Nursing

An **ethical dilemma** is a conflict between two sets of human values, both of which are judged to be “good” but neither of which can be fully served. Ethical dilemmas can cause distress and confusion for patients and caregivers. You may well be faced with ethical questions that have not been examined previously and for which no practical wisdom exists. You must be able to examine issues and apply experience and wisdom in each situation. The CNA (2008) *Code of Ethics* identified the responsibility of nurses to maintain their “fitness to practise” as having the “necessary physical, mental or emotional capacity to practise safely and competently” (p. 18). Such fitness requires you to be knowledgeable and skillful as you engage in problem solving. Ethical issues must be analyzed carefully and deliberately. Ethical analysis involves descriptive, conceptual, and normative processes. Analysis of situations begins with acquiring knowledge to gain a sense of what is going on (descriptive analysis), as well as finding out about relevant policies, laws, relationships, and stakeholders. Conceptual analysis is clarifying the meaning of the situation, values, and assumptions of all individuals involved. Normative analysis focuses on what ought to be done, based on the people involved and the values of the people (Yeo, et al., 2010).

Resolving an ethical dilemma requires deliberate, critical, and systematic thinking (Box 7-4). It also requires negotiation of differences (between beliefs, values, opinions, and so forth), incorporation of conflicting ideas, and an effort to respect differences of opinion. The process of negotiating ethical dilemmas may be in part the process of understanding ambiguities. You need to be knowledgeable and adept in making logical, fair, and consistent decisions. Ethical decision-making models offer a variety of methods for reaching informed conclusions (Box 7-5).

► BOX 7-4 How to Analyze an Ethical Dilemma

- Step 1:** Determine whether the issue is an ethical dilemma.
- Step 2:** Gather all the information relevant to the case.
- Step 3:** Examine and determine your own values on the issues.
- Step 4:** Verbalize the problem.
- Step 5:** Consider possible courses of action.
- Step 6:** Reflect on the outcome.
- Step 7:** Evaluate the action and the outcome.

► BOX 7-5 Two Ethical Decision-Making Frameworks

1. Information & Identification

- Concern
- People/population
- Ethical components

2. Clarification & Evaluation

3. Action & Review

Diagram on left: From Storch, J. L. (2004). Model for ethical decision making for policy and practice. In J. Storch, P. Rodney, & R. Starzomski (Eds.), *Toward a moral horizon: Nursing ethics for leadership and practice* (p. 515). Toronto: Pearson Education. **Diagram on right:** From College and Association of Registered Nurses of Alberta. (2010). A model for questioning. In *Ethical decision-making for registered nurses in Alberta: Guidelines and recommendations* (p. 13). Edmonton: Author. Reprinted by permission of College and Association of Registered Nurses of Alberta.

Documentation of the ethical process can take a variety of forms. Whenever the process involves a family conference or results in a change in the plan of care, the process should be documented in the medical record. At some institutions, the ethics committee may use a formal consultation format whenever a request for discussion arises. If the ethical dilemma does not directly affect patient care, however, discussion may be documented by minutes from a meeting or in a memorandum to affected parties. In the following case study, the nursing concerns and the family conferences would be recorded in the medical record and in nursing flow sheets.

On your unit, a 35-year-old woman has been hospitalized in the final stages of brain cancer. She is a single mother with two young children. Although she has been treated by both conventional and experimental treatments, the tumour continues to grow, and the medical team has agreed that further treatment would be futile. You have cared for this patient during past hospital admissions, and during an especially open discussion, she expressed wishes to explore "do not resuscitate" (DNR) orders. During the current admission, her primary physician is out of town. The attending physician does not know the patient personally, but he has spent time with her. He has reviewed the clinical data and agrees that the patient is entering the terminal stage of the disease. In his opinion, however, the patient is not ready to discuss end-of-life issues. He states that the patient has declined to discuss DNR orders with him. You ask the physician to convene a family conference about the issues. He refuses, stating that he believes the patient is not ready to participate.

Step 1: Is this an ethical dilemma? What may at first appear to be a question of ethics may be resolved by clarifying your knowledge about clinical facts. A review of policy and procedure, or of standards of care, may reveal legal obligations that determine a course of action, regardless of personal opinion.

If the question remains perplexing, and the answer will be profoundly relevant to several areas of human concern, then an ethical dilemma may exist.

The single mother's situation meets the criteria for an ethical dilemma. Further review of scientific data will probably not contribute to a resolution of the dilemma, but it is important to review the data carefully to make this determination. The disagreement does not revolve around whether the patient is in a terminally ill state, so further clinical information will not change the basic question: Should the patient have an opportunity to discuss DNR orders at this time? The question is perplexing. Two professional team members disagree on an assessment of a patient's readiness to confront the difficult issues related to dying. The answer to the question "Is this patient ready to discuss end of life?" has important implications. If she is not ready, then raising the issue may cause anguish and fear in the patient and her family. If she is ready and the team avoids discussion, she may suffer unnecessarily in silence. If she is very close to death, then in the absence of a DNR order, necessitate cardiopulmonary resuscitation (CPR) will be performed in a futile situation. You know that CPR can cause pain. If applied in a situation in which the patient's life is unlikely to be extended or improved, CPR could prolong her suffering and reduce her dignity.

Step 2: Gather as much information as possible that is relevant to the case. Because resolution to dilemmas may arise from unlikely sources, incorporate as much knowledge as possible at every step of the process. At this point, the information could include laboratory and test results, the clinical state of the patient, and current literature about the diagnosis or condition of the patient. It may include investigation of the psychosocial concerns of the patient, as well as those of her significant others. The patient's religious, cultural, and family orientations are part of the nurse's assessment.

You obtain all the clinical information that is pertinent to the question. It may be helpful to determine whether the patient retains most cognitive functions, even though her tumour is aggressive. You review the chart and discuss this aspect with the physician, and you agree that the patient is fully competent but afraid and overwhelmed by the prognosis. Because two professionals disagree on a patient's state of mind, it may be helpful to reassess the patient or request that an independent person assess the patient's readiness to discuss end-of-life issues. Sometimes family members or significant others hold important clues to a patient's state of mind.

Step 3: Examine and determine your own values on the issues. This step is important for all participants in the discussion. At this stage, you and the other participants practise values clarification, and you differentiate between your own values and the values of the patient and of other health care team members. Essential parts of the goal are to form your own opinion and to respect others' opinions.

At this point, you stop to reflect on your own values. Your own religious practices may allow you to decide to forgo further treatment if you were in the patient's condition. You also may not yet have family members who rely on you, such as children or elderly parents. This patient's religious practices may be more strictly constructed than your own. Her religion discourages actions that diminish life in any way, and you realize that she may have come to see a DNR order as giving up, or as "acting like God." In addition, you understand that the attending physician has not had time to know this patient as her own physician has or as you have. You continue to believe that the patient would be capable of a discussion, despite her statements to the physician. In fact, you believe that she would benefit from a discussion, because perhaps the presence of an unfamiliar caretaker, combined with declining physical health, has silenced her, even though her fears and concerns persist.

Step 4: Verbalize the problem. Once all relevant information has been gathered, accurate definition of the problem may proceed. It is helpful to state the problem in a few sentences. By agreeing to a statement of the problem, the health care team, the patient, and the family can proceed with discussion in a focused way.

Here, the problem seems to be this: whether this patient should discuss DNR at this time. Determine the benefits and risks of a DNR order at this time. Other important questions relate to the patient's current state of mind: Is she afraid to speak? Is she feeling cut off from her normal network (a primary physician)? Are these feelings contributing to confusion about DNR decisions?

Step 5: Consider possible courses of action. What options are available within the context of the situation and the patient's values?

Once you have asked the basic question, other questions and possible courses of action arise. Should you initiate a discussion with the patient independently of the physician? Would you be outside your professional role if you facilitated a DNR order? What if your assessment were incorrect? Would you contribute not to the dignity but to the distress of the patient? The answers to these questions may be elusive, because they depend on an understanding of the patient's feelings and values that are not necessarily obvious. Even if the nurse cannot legally write a DNR order, the nurse can influence a physician's or patient's decision regarding DNR; therefore, troubling questions remain.

Step 6: Reflect on the outcome. This is the most important and delicate step of the process. These negotiations may happen informally at the patient's bedside or in the charting room, or

a formal ethics meeting may be necessary. Your point of view represents a unique contribution to the discussion.

In an ethics committee meeting, the discussion is usually multidisciplinary. A facilitator or chairperson ensures that all points of view are examined and that all pertinent issues are identified. A decision or recommendation is the usual outcome of discussion and the result of a successful discussion. In the best of circumstances, participants discover a course of action that meets criteria for acceptance by all. On occasion, however, participants may leave the discussion disappointed or even opposed to the decision.

The discussion focuses on the disagreement between your assessment and the physician's regarding the patient's readiness to discuss end-of-life issues. The principles involved during the discussion include beneficence and nonmaleficence: Which plan would provide the most good for this patient—a DNR order or no order? A separate question addresses the patient's point of view: Would a discussion with the patient promote well-being or promote anguish? Furthermore, according to the principle of autonomy, a troublesome question remains: Does the patient want something different from the desire she is expressing?

With several members of the health care team present, the discussion proceeds. You present your point of view. You continue to sense that the patient is ready to discuss DNR orders but that she may be reluctant to trust the circumstances of this admission. You respect the attending physician and his analysis and continue to be concerned that the patient may have experienced a change of mind between the last admission and this one. In the end, the team proposes a formal meeting with the patient, in which you, the attending physician, and a supportive family member are present. You support this proposal because you sense that it will maximize the support of the patient's existing network. In addition, you recognize that in a trusting environment, the patient is more likely to express fears, insecurities, and wishes. Team members agree to keep the discussion open-ended and exploratory. You suggest that rather than asking whether the patient wants a DNR order, the team could wait for her to bring up the issue. In this way, the team could be assured of her consent and willingness to participate in the discussion.

Step 7: Evaluate the action and the outcome.

At the meeting, the patient in fact opens up. She expresses relief at the chance to explore her options and feelings. Pain management issues are clarified. She wants to discuss a DNR order but requests a visit from her priest before she must make a final decision.

Ethical Issues in Nursing Practice

With increased professional responsibility and accountability, and with changes in the workplace and health care system, you are increasingly facing a myriad of ethical issues. You face ethical issues daily while caring for patients and families, while relating to other health care providers, institutions, and global societal issues. The following section explores current issues in which ethical issues arise.

Patient Care Issues

Informed Consent. The intimacy and integrity of the nurse-patient relationship mandate that you protect the rights of your patients. You achieve this mandate as you follow standards, policies, guidelines, and legislation regarding consent

to treatment. **Informed consent** is consent to treatment on the basis of accurate and complete information (see Chapter 8). The goal of informed consent is to protect the patient's right to autonomy. The CNA (2008) *Code of Ethics* (p. 11) asserts that to promote and respect informed decision making, some of the nurse's ethical responsibilities are as follows:

- Building trusting relationships to ensure that the patient's choice is understood, expressed, and advocated
- Providing the desired information and support so that patients can make informed decisions
- Assisting patients in obtaining the most accurate current knowledge about their health condition
- Being sensitive to the inherent power differentials between health care providers and patients: nurses must not misuse power to influence decision making
- Recognizing that the patient has the right to refuse or withdraw consent
- Respecting the informed choices of capable persons, including choice of lifestyles or of treatment not conducive to good health

Many unethical scenarios can involve consent: a patient's signing consent forms without understanding what treatment entails; a nurse's mistaken assumption that a physician has explained a medical procedure to a patient before obtaining the patient's consent; obtaining consent from a patient who does not speak the health care team's language without the assistance of an interpreter; or a patient's consenting to a procedure without knowing about associated risks or potential adverse side effects.

Although obtaining informed consent for medical procedures is not a nursing duty, you may witness the patient's signature on the consent form. When you provide consent forms for patients to sign, your main responsibility lies with ensuring that the patient fully understands the nature of the treatment or procedure. If not, notification of the physician must occur so that the physician can clarify or provide additional information.

Futile Care. In the early 1980s, issues such as enhanced life-sustaining technologies, patients' rights movements, and growing concerns about using health care resources in a cost-effective and efficient manner led to academic discussions, debates, and practice policies on medical futility. **Medical futility** is defined as a medical treatment that is considered impossible or unlikely to achieve its therapeutic goal, or suggests that there is something problematic about the goal (Browne, 2000). Patients often worry, in the event of their becoming incapacitated and unable to express their wishes, that they will be "hooked up to machines" and receive treatment that they do not desire (Figure 7-1). At issue is whether clinicians are sufficiently objective to establish that a given intervention is futile as determinations of futility are often laden with biases.

Although health care providers are best equipped to determine the physical benefits of treatment, only the patient or people who know the patient best can determine whether treatment is advancing the patient's overall wellbeing. Bennett Jacobs and Taylor (2005a) identified this issue as "qualitative" futility or subjective determination, in which not just medical facts but also values lead the patient or the patient's surrogate decision makers to conclude that the treatment has no benefit according to those values (Ulrich et al., 2010).

Achieving holistic outcomes of care must be based on an interplay of physical facts and subjective values. Taylor (1995)

Figure 7-1 Nurses often struggle when patients are receiving care that they believe is prolonging their suffering and their life.

suggested the following four classifications of futility: (1) not futile: beneficial to both physical and overall well-being; (2) futile: nonbeneficial to either physical or overall well-being; (3) futile from the patient's perspective: medically indicated but not valued by the patient; and (4) futile from the clinicians' perspective and not medically indicated but valued by the patient (p. 301). It is evident that these classifications have objective and subjective dimensions, as well as quantitative and qualitative dimensions, and constitute a more complete way of viewing the complex notion of futility.

The issue of who has priority in health care decision making remains complex and often troublesome. The potential for futility conflicts is high in situations of critically and chronically ill patients. What, then, is your role? Taylor (1995) suggested that nurses play a leading role in working toward pursuing negotiated compromise between health care providers and patients equally, for the best possible outcome for the particular patient. She suggested that this may be accomplished "by identifying patients, families, and health care teams at risk of experiencing conflict about futile care, and then initiating dialogue that may prevent or resolve conflict" (p. 303). Rather than subscribing to categories of levels of futility to drive decision making, many health care agencies have now developed end-of-life guidelines that are tailored to patients' needs. These guidelines include a determination of levels of intervention or goals of care that range from fully acute to palliative/comfort care (Rocker & Dunbar, 2000). Levels of intervention are based on the premise that specific interventions may either be withheld or administered based on individual patient needs, and that supportive/palliative care ought to be integrated with all levels. **Advance directives** are one way to address this problem (see Chapter 8). They are people's preferences, wishes, and likely plans in the event that they become incapable of expressing those wishes for themselves. Advance directives are commonly expressed in two ways: (1) an instruction directive, or living will, that identifies what life-sustaining treatment a patient desires in certain situations, and (2) a proxy decision maker who knows the person well and speaks for his or her best interests. Advance directives have the potential to facilitate communication about the withholding or withdrawing of treatment, even though these

directives are not codified in law in every Canadian province (Blondeau et al., 2000). A routine part of any admission to a hospital now usually includes inquiry about the patient's advance directives; if they exist, they are included as part of the medical record. It has become necessary for nurses to be aware of the legal status of all types of advance directives in their province or territory.

You have several roles regarding advance directives. You may be involved in helping patients plan an advance directive by discussing its uses and helping patients to clarify their values and wishes for end-of-life treatment. Your role also includes following the advance directive, alerting other health care providers to changes in the patient's wishes, and advocating on behalf of the patient or substitute decision maker if the patient's wishes or advance directive are not being followed.

Withdrawal of Food and Hydration. Maintaining nutrition is a natural life-sustaining measure and common part of the nursing role. A change in the patient's ability to drink and eat raises many issues. When food and hydration are administered for a prolonged period to a patient whose condition is not expected to improve, some nurses may view this care as extraordinary or heroic, whereas others see this as humane.

Current literature suggests that fluids should not be routinely administered to dying individuals or automatically withheld from them; rather, they should be given on the basis of the goals of care and a careful assessment of the patient's comfort. A position statement by the CNA (2001) on utility stresses the importance of the health care team to determine whether food and fluid are most beneficial or harmful to a patient. The following questions may aid health care providers in reflecting on the goals of care: Will the patient's well-being be enhanced by the administration of nutrition? Does the patient have symptoms that could be relieved or aggravated by the administration of nutrition? Could hydration enhance the patient's mental status or level of consciousness? Will it prolong the patient's life? Is that the wish of the patient and family (Bennett Jacobs & Taylor, 2005b; Ganzini, 2006)?

The administration of hydration may raise dilemmas when its use is intended merely to maintain physical life (e.g., when the patient is in a vegetative state or is near death). You should know that during the natural dying process, the body starts to "shut down," and the patient may lose the desire for food and fluids. Force-feeding a dying patient may sometimes do more harm than good. Withholding or withdrawing nutrition or hydration from a patient is no different from the decision to forgo any other medical treatment that may prolong the dying process. It is considered appropriate to withhold or discontinue life-sustaining medical interventions if they are not benefiting the patient or are contrary to the patient's wishes. Furthermore, it is important to stress to families that dying individuals who are not receiving artificial nutrition or hydration will still be provided with adequate overall care.

Issues of Safety in the Work Environment

Nurses are responsible for providing safe, compassionate, competent, and ethical care (CNA, 2008). In ensuring safety, care must be such that harm is minimized. Lack of control over important aspects of the environment can lead to ethically ambiguous situations (Austin, 2007). Complex life-and-death events, multiple role responsibilities, loyalties and expectations, reduced numbers of skilled health care providers, minimal clinical nursing leadership, interdisciplinary team

conflict, and autocratic organizational decision making may create personal moral conflict for you (Austin, 2007; Canadian Health Services Research Foundation, 2006).

Causing harm to patients in the form of pain and suffering from continuing treatment is a source of **moral distress** for nurses that they often believe could be avoided. "Moral distress arises in situations where nurses know or believe they know the right thing to do, but for various reasons (including fear or circumstances beyond their control), do not or cannot take the right action to prevent a particular harm" (CNA, 2008, p. 6). Sometimes nurses find it hard to care for a patient when other health care providers, usually physicians, make choices that nurses think are causing more harm than good. For example, the situation of a patient in intensive care who is comatose but seems to experience great pain when turned over can be very upsetting for nurses. They may experience moral distress if they feel that they are, in effect, torturing the patient each time they turn him or her over. Keeping patients safe from harm can be difficult, and sometimes it requires great ethical sensitivity to be aware of harms that are being caused. In these situations, nurses may lose their sense of **moral integrity** or "wholeness" when they are committed to certain values and beliefs that are not upheld because of situational constraints. If these situations continue and integrity is compromised, nurses may experience **moral residue**, when they seriously compromise themselves or allow themselves to be compromised (CNA, 2008, p. 7). Relational ethics helps you know what the patient considers harm, and it is crucial to engage in discussions with your patients and colleagues.

Other kinds of harm can come to patients because of inadequate or inappropriate caregiving. Sometimes harm results from mistakes that can be explained; sometimes it results from carelessness or incompetence. For example, when you have a lot of very ill patients to care for and you have many demands on your time, medication errors can occur because you are distracted and feeling rushed. These kinds of errors are unfortunate, but they are not breaches of ethics as such. On the other hand, if you make a medication error because you have been out partying all night before your shift and you were not fit to practise that day, the error would be considered unethical. Either way, you need to monitor your own competence to practise, and you must admit to your mistakes. Regardless of the cause, if you make a mistake, not admitting it is considered unethical.

In a multidisciplinary environment, all health care providers must take responsibility for the care that is provided (Boxes 7-6 and 7-7). You need to be aware of what other providers are doing for and with their patients. If **adverse events** occur—that is, "unexpected, undesirable incidents resulting in injury or death that are directly associated with the process of providing health care or services to a person receiving care" (CNA 2008, p. 18)—then you must report them, regardless of who is responsible. The person who is most directly involved when an adverse event occurs should be the one to report it, but sometimes that does not happen. In that situation, if you observe the event, you must report it. It is your obligation to ensure patient safety, but it is not easy because it can mean exposing the incompetence of a colleague. Imagine, for example, that you observe another nurse drop a frail elderly patient during transfer. The patient does not seem hurt, and the other nurse does not seem to plan to report the incident. Should you report it yourself? Your obligation is to speak to the other nurse and ensure that the incident is reported. If the

* BOX 7-6 RESEARCH HIGHLIGHT

Ethics in Nursing Practice

Research Focus

Gaudine et al. (2011) were interested in exploring ethical conflict of nurse and physician participants from four university teaching hospitals, located in Atlantic Canada and central Canada, about their ethical conflicts in clinical situations and with the organization, and their perceptions of barriers to consulting the clinical ethics committees in their hospitals.

Research Abstract

Much of the literature on clinical ethical conflict has been specific to a specialty area or a particular patient group, as well as to a single profession. This Canadian study identified themes of hospital nurses' and physicians' clinical ethical conflicts that cut across the spectrum of clinical specialty areas, and compared the themes identified by nurses with those identified by physicians. The authors interviewed 34 clinical nurses, 10 nurse managers, and 31 physicians working at four different Canadian hospitals as part of a larger study on clinical ethics committees and nurses' and physicians' use of these committees. They described nine themes of clinical ethical conflict that were common to both hospital nurses and physicians, and three themes that were specific to physicians. Finally the authors suggested reasons for differences in nurses' and physicians' ethical conflicts and discussed implications for practice and research.

Evidence-Informed Practice

A few common themes of ethical conflict are these:

- Disagreement about care decisions or treatment options
- Others not respecting a patient's wishes
- Patient not receiving quality end-of-life care

"Striving to do what is best for the patient" underpins all the clinical ethical conflict. Overall, there are more similarities than differences in the clinical ethical conflicts experienced by nurses and physicians.

Many clinical situations described by the participants included more than one theme of ethical conflict. This suggests the complexity and interrelatedness of ethical concerns experienced in the day-to-day provision of care. One clinical situation can present a myriad of ethical concerns.

Both the nurses and the physicians gave examples of "disagreement about care decisions or treatment options." This may be surprising, because physicians typically make the decisions. However, there are many levels of physician care (clinical associate, clerk, consulting physicians) wherein physicians may not be in charge of the patient's care and thus may not agree with treatment decisions.

Nurses reported conflict not only with physicians but also with other health care providers. This may reflect the evolving nature of interprofessional teams and the complexities of collaboration across health disciplines.

Reference: Gaudine, A., Lefort, S., Lamb, M., & Thorne, L. (2011). Clinical ethics conflict of nurses and physicians. *Nursing Ethics*, 18(1), 9–19.

nurse does not report it, then you must do so, inasmuch as this is a clear issue of patient safety, and your obligations are clear. **Whistle blowing** (i.e., reporting a colleague's errors, incompetence, unsafe or negligent practice, or abuse of patients) is one of the most difficult actions you must take in ensuring that safe, compassionate, competent, and ethical care is met (Oberle & Raffin Bouchal, 2009).

* BOX 7-7 FOCUS ON PRIMARY HEALTH CARE

How to Encourage Nurses Individually and Collectively to Work Toward Eliminating Social Inequities

- Utilize the principles of primary health care for the benefit of the public and patients receiving care.
- Understand that some groups in society are systemically disadvantaged, which leads to poorer health and diminished well-being. Nurses work to improve the quality of lives of people who are part of disadvantaged and vulnerable groups and communities, and they take action to overcome barriers to health care.
- Recognize and work to address organizational, social, economic, and political factors that influence health and well-being within the context of your role in the delivery of care.

* KEY CONCEPTS

- Values clarification helps nurses explore personal values and feelings and to decide how to act on personal beliefs. It also facilitates nurse-patient communication.
- Ethics is the study of philosophical ideals of what is beneficial or valuable for all.
- A code of ethics provides a foundation for professional nursing. Such a code promotes accountability, responsibility, and advocacy.
- Theories of bioethics refer to ethical issues specific to the delivery of health care. They are based on the principles of autonomy, beneficence, nonmaleficence, and justice.
- Relational ethics theory encompasses more than bioethics: it addresses the role of relationship in the ethical delivery of health care. It maintains that the nurse-patient relationship is the foundation of nursing ethics.
- Ethical problems arise from differences in values, from technological advances, from end-of-life experiences, and from changes in work environments.
- A standard process for thinking through ethical dilemmas, including critical thinking skills, helps health care providers resolve conflict or uncertainty about correct actions.

* CRITICAL THINKING EXERCISES

1. Complete the values clarification exercise (Box 7-1) with your classmates or others. Compare the answers and discuss the differences.
2. You are a clinic nurse in a small community clinic. A 17-year-old female patient has been coming to the clinic for treatment for and support with a sexually transmitted infection. During recent months, she has lost her support from a close friend. In addition, her parents are divorced, and she has little contact with them. Her health and well-being are of concern. Her appearance is unkempt, her nutritional status is not balanced, and she has admitted to being depressed. She asks for your help in planning her suicide. Discuss your response to her request. Begin by acknowledging the laws related to assisted suicide in Canada. Examine your personal feelings about suicide. Include a discussion about your understanding of sexually transmitted infections: Where do they come from? Who gets these infections? Why do people get

these infections? What are your feelings and opinions about people with sexually transmitted infections? Construct your response, keeping in mind the theory of relational ethics. Discuss your role in this situation. What are your possible courses of action?

3. You have been assigned the care of a 98-year-old woman who was recently admitted with a diagnosis of pneumonia. She has a history of cardiac disease and takes a number of medications. She had been fairly active until the past few days, when her cough worsened and a fever developed. You note that her pulse has become weak and threadlike and that her respirations are increasingly laboured. The patient is now too weak to respond to you. When you mention to the family that you may need to call the physician and even take heroic life-saving measures, the patient's son and daughter become distraught, saying that they do not want their mother to be kept alive on "machines." They report that they have discussed this situation with their mother. You find that her wishes have not been documented in her chart. The family members have not discussed this situation with the patient's primary physician. What actions would you consider taking at this moment? Take into account the ethical principles of autonomy and beneficence and the idea of futile care. What are your personal values about interventions at the end of life?

✦ REVIEW QUESTIONS

1. Values clarification plays a major role in
 1. Creating a set of rules for conduct
 2. Identifying values that should be accepted by all
 3. Resolving issues of "value conflict"
 4. Developing a code of ethics
2. In Canada, equitable access to health care means that all citizens have equal access to medically necessary services. Many jurisdictions have implemented private magnetic resonance imaging clinics. A discussion about the ethics of this situation would involve predominately the principle of
 1. Accountability
 2. Autonomy
 3. Relational ethics
 4. Justice
3. It may seem redundant when health care providers, including professional nurses, agree to "do no harm" to their patients. The point of this agreement is to reassure the public that in all ways, not only will the health care team work to heal patients but they also agree to do this in the least painful and harmful way possible. The principle that describes this agreement is called
 1. Beneficence
 2. Accountability
 3. Nonmaleficence
 4. Respect for autonomy
4. Vaccination may cause temporary discomfort, but the benefits of protection from disease, both for the individual and for society, outweigh the patient's discomfort. This involves the principle of
 1. Beneficence
 2. Fidelity
 3. Nonmaleficence
 4. Respect for autonomy
5. If a nurse assesses a patient for pain and then offers a plan to manage the pain, the principle that encourages the nurse to monitor the patient's response to the plan is
 1. Beneficence
 2. Justice
 3. Nonmaleficence
 4. Respect for autonomy
6. Including patients in decision making regarding their care and respecting their choices of treatment demonstrate the principle of
 1. Beneficence
 2. Autonomy
 3. Justice
 4. Veracity
7. Nurses agree to be advocates for their patients. Practice of advocacy calls for the nurse to
 1. Seek out a nursing supervisor in situations involving conflict
 2. Work to understand the law as it applies to the patient's clinical condition
 3. Assess the patient's point of view and prepare to articulate this point of view
 4. Document all clinical changes in the medical record in a timely manner
8. Which of the following is *not* part of the nurse's role as patient advocate?
 1. Intervening if other people fail to respect the patient's dignity
 2. Protecting the patient's right to confidentiality and privacy
 3. Making nursing care decisions for the patient
 4. Advocating for appropriate use of interventions to minimize suffering
9. The philosophy of relational ethics suggests that ethical dilemmas can best be solved by attention to
 1. Relationships
 2. Ethical principles
 3. Patients
 4. Code of ethics for nurses
10. Ethical dilemmas often arise over a conflict of opinion. Once the nurse has determined that the dilemma is ethical, a critical first step in negotiating the difference of opinion is to
 1. Consult a professional ethicist to ensure that the steps of the process occur in full
 2. Gather all relevant information regarding the dilemma
 3. List the ethical principles that inform the dilemma so that negotiations agree on the language of the discussion
 4. Ensure that the attending physician has written an order for an ethics consultation to support the ethics process

✦ RECOMMENDED WEB SITES

Canadian Bioethics Society: <http://www.bioethics.ca>

Founded in 1988 through the amalgamation of the Canadian Society of Bioethics and the Canadian Society for Medical Bioethics. Members include health care administrators, lawyers, nurses, philosophers, physicians, theologians, and other professionals concerned with the ethical and humane

dimensions of health care. The Web site offers information about the annual CBS conference, national and international ethics organization links, and relevant ethics journals from a variety of disciplines.

Canadian Nurses Association—Code of Ethics: http://www2.cna-aiic.ca/CNA/practice/ethics/code/default_e.aspx

Provides a link to the CNA and the *Code of Ethics for Registered Nurses* (CNA, 2008).

W. Maurice Young Centre for Applied Ethics: <http://www.ethics.ubc.ca>

Established by the University of British Columbia in 1993; primarily an interdisciplinary research centre in which a variety of ethics topics are studied. The Web site has links to other ethics organizations and ethics resources. The centre's newsletter is also available on the Web site.

Nursing Ethics.ca: <http://www.nursingethics.ca/>

The page has links to Canadian resources that support ethical nursing practice.

Provincial Health Ethics Network of Alberta (PHEN): <http://www.phen.ab.ca/>

Established as a society in 1995; provides information for all Albertans about ethics and access to health ethics resources. Its mission is to facilitate examination, discussion, and decision making with regard to ethical issues in health and health care.

Legal Implications in Nursing Practice

Written by Carla Shapiro, RN, MN

Based on the original chapter by Christine R. Durbin, RN, PhD, JD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Explain legal concepts that apply to nurses.
- Describe the legal responsibilities and obligations of nurses.
- List sources for standards of care for nurses.
- Define legal aspects of nurse–patient, nurse–physician, nurse–nurse, and nurse–employer relationships.
- List the elements needed to prove negligence.
- Give examples of legal issues that arise in nursing practice.

key terms

Safe nursing practice includes knowledge of the legal boundaries within which nurses must function. Nurses must understand the law to protect themselves from liability and to protect their patients' rights. Nurses need not fear the law; rather, they should view it as representing what society expects from them. Laws are continually changing to meet the needs of the people they are intended to protect. As technology has expanded the role of the nurse, the ethical dilemmas associated with patient care have increased and often become legal issues as well. As health care evolves, so do the legal implications for health care. Although federal laws apply to all provinces and territories, nurses must also be aware that laws do vary across the country. It is important for nurses to know the laws in their province or territory that affect their practice. Being familiar with the law enhances nurses' ability to be patient advocates.

Legal Limits of Nursing

Nurses have a fiduciary relationship with their patients. A fiduciary relationship is one in which a professional (the nurse) provides services that, by their nature, cause

the recipient (the patient) to trust in the specialized knowledge and integrity of the professional. In the fiduciary relationship, nurses are obligated to provide knowledgeable, competent, and safe care.

Although legal actions against nurses were once rare, the situation is changing. The public is better informed now than in the past about their rights to health care and are more likely to seek damages for professional negligence. The courts have upheld the concept that nurses must provide a reasonable standard of care. Thus, it is essential that nurses understand the legal limits influencing their daily practice.

Sources of Law

The Canadian legal system can be divided into two main categories: public law and private law. Public law is chiefly concerned with relations between individuals and the state or society in general and includes constitutional, tax, administrative, human rights, and criminal law. Private law involves disputes between individuals and covers issues such as wills, contracts, marriage and divorce, and civil wrongs (e.g., negligence). Whereas public law is addressed in the same manner across the country, two systems deal with private law issues—**civil law** (based on Roman law) in Quebec and **common law** (based on British common law) throughout the rest of the country. These two systems differ primarily in their legal processes. In each system, courts interpret the rules made by the legislature in the context of specific disputes.

When either a civil or a criminal case goes to court, decisions are based on previous case rulings. How courts rule on the circumstances and facts surrounding the case is called a *precedent*. If a case is decided on the basis of certain facts, the court is bound to follow that decision in subsequent similar cases. Not every jurisdiction has case law on a given issue. For example, cases regarding a patient's right to refuse treatment are not found in every province. In such situations, other jurisdictions are consulted for guidance. In general, breaches of private law result in the payment of money to compensate the aggrieved party for damages incurred. Violations of public law may result in a range of remedies, including fines or imprisonment.

Statute law is created by elective legislative bodies such as Parliament and provincial or territorial legislatures. Federal statutes apply throughout the country, and provincial and territorial statutes apply only in the province or territory in which they were created. Examples of provincial statutes are the *Regulated Health Professions Act* (1991) in Ontario and nursing practice acts throughout the country, which describe and define nursing practice within each province.

Examples of federal statutes are the new *Assisted Human Reproduction Act* (2004), the *Controlled Drugs and Substances Act* (1996), and the *Food and Drugs Act* (1985).

Professional Regulation

Like all self-governing professions in Canada, nursing is regulated at the provincial or territorial level. Each province and territory has legislation that grants authority to a nursing regulatory body. These regulatory bodies are accountable to the public for ensuring safe, competent, and ethical nursing care. Regulatory bodies are responsible for granting certificates of registration, offering practice support, ensuring continuing competence of its members, investigating complaints against members' conduct, and disciplining members when necessary. Regulatory bodies are also responsible for developing codes of

ethics, setting standards of practice, and approving nursing education programs (McIntyre, & McDonald, 2010).

Separate regulatory bodies exist for registered nurses and practical nurses. Some provinces also have regulatory bodies for registered psychiatric nurses. These regulatory bodies are called either the *provincial association* or the *college of nursing* (e.g., the Alberta Association of Registered Nurses, the College of Licensed Practical Nurses of Alberta, the College of Nurses of Ontario). The trend appears to be a move to the college model, with a stronger focus on regulation of practice and accountability to the public.

Nurses must be registered by the professional nursing association or college of the province or territory in which they practise. The requirements for registration (or licensure, as applicable) vary across the country, but most provinces and territories have minimum education requirements and require the nurse to pass an examination. All provinces and territories (except Quebec) use the Canadian Registered Nurse Examination. Quebec has created its own examination. Registration (or licensure) enables people to practise nursing and use the applicable nursing title and initials: registered nurse (RN) or registered practical nurse (RPN). All nurses' credentials must be verified, either by the listing of their names on a register or by their holding a valid licence to practise.

Registration can be suspended or revoked by the regulatory body if a nurse's conduct violates provisions in the registration statute. For example, nurses who perform illegal acts, such as selling controlled substances, jeopardize their registration status. Due process must be followed before registration can be suspended or revoked. *Due process* means that nurses must be notified of the charges brought against them and have an opportunity to defend themselves against the charges in a hearing. Such hearings do not occur in courts but are usually conducted by the regulatory body. If a nurse loses his or her professional licence, or if the nurse's name is removed from the provincial or territorial register, and if the case involves civil or criminal wrongs, then further legal consequences may follow.

Regulation of Nurse Practitioners

Over the past number of years, the role, responsibilities and use of nurse practitioners (NPs) has evolved in Canada. The utilization and regulation of NPs varies from jurisdiction to jurisdiction across the country. In some provinces or territories (e.g., Newfoundland, Northwest Territories, Nunavut), the title "nurse practitioner" is protected, and in others (e.g., Manitoba) these nurses are identified in other ways such as RN/EP (Extended Practice) or RN/NP (nurse practitioner). It is important that nurses communicate their regulated title to their patients, families, and other members of the health care team. The differences in regulatory approaches among jurisdictions can be confusing to consumers and can affect the mobility of nurses across the country as a result of this (McIntyre & McDonald, 2010).

Standards of Care

Standards of care are legal guidelines for nursing practice. Standards establish an expectation of nurses to provide safe and appropriate patient care. If nurses do not perform duties within accepted standards of care, they may place themselves in jeopardy of legal action and, more important, place their patients at risk for harm and injury. Nursing standards of care arise from a variety of sources, including statutes and laws of

broad application, such as the statutes and common law relating to human rights, privacy, and negligence; provincial statutes that specifically apply to health care professionals or nurses only; and the detailed regulations, practice standards, and codes of ethics that are generated by the professional associations. Nursing standards are also outlined in the written policies and procedures of employing institutions.

All provincial and territorial legislatures have passed health professions, **nursing practice acts**, or both that define the scope of nursing practice. These acts set educational requirements for nurses, distinguish between nursing and medical practice, and generally define nursing practice. The rules and regulations enacted by the provincial or territorial regulatory body help define the practice of nursing more specifically. For example, a nursing association may develop a rule regarding intravenous therapy. All nurses are responsible for knowing the provisions of the nursing practice act for the province or territory in which they work, as well as the rules and regulations enacted by the regulatory administrative bodies of their province or territory.

Professional organizations are another source for defining standards of care. The Canadian Nurses Association (CNA) has developed standards for nursing practice, policy statements, and similar resolutions. The standards delineate the scope, function, and role of the nurse in practice. Nursing specialty organizations also have standards of practice defined for certification of nurses who work in specific specialty areas, such as the operating room or the critical care unit. The same standards also serve as practice guidelines for defining safe and appropriate nursing care in specialty areas.

The Canadian Council on Health Services Accreditation requires that accredited health care institutions have nursing policies and procedures in writing that detail how nurses are to perform their duties. These internal standards of care are usually quite specific and are found in procedural manuals on most nursing units. For example, a procedure or policy that outlines the steps that should be taken when a dressing is changed or medication is administered gives specific information about how nurses are to perform these tasks. Nurses must know the policies and procedures of their employing institution because they all must follow the same standard of care. Institutional policies and procedures must conform to laws and cannot conflict with legal guidelines that define acceptable standards of care.

In a negligence lawsuit, these standards are used to determine whether the nurse has acted as any reasonably prudent nurse in a similar setting with the same credentials would act. A nursing expert is called to testify about the standards of nursing care as applied to the facts of the case (Box 8-1). The expert may be called to define and explain to the court what a reasonably prudent nurse would have been expected to do in view of the facts of the case in any similar setting around the country. It is recognized and understood that nursing practice differs according to the rural or urban nature of the institutional setting. In addition, home health care, occupational health nursing, and other community-based clinical settings require that the expert be familiar with the standards of care in these settings, as opposed to the traditional hospital or institutional setting. The expert must have the appropriate credentials, the appropriate experience, and an understanding of what the standard of care should have been in the specific case. The expert witness is distinguished from the fact witness. Staff nurses may testify in a court proceeding as fact witnesses if they have first-hand personal experience with the facts of the

► BOX 8-1

Anatomy of a Lawsuit

Pleadings: Statements of Claim and Defence

- The plaintiff outlines what the defendant or defendants did wrong and how that action caused injury.
- The statement of claim is then issued by the court and served on the defendant or defendants.
- Statements of claim are often very broad and may be served on the employer, institution, and all members of the health care team involved in the patient's care at the relevant time.
- The defendant or defendants must deliver a statement of defence to the allegations. The defendant or defendants can admit or deny each allegation in the petition.

Procedures of Discovery

Pretrial proceedings enable each side to gather legally relevant information from the other side and usually lead to a settlement between the parties before a trial.

1. *Examination for discovery:* The plaintiff's lawyer is permitted to question each defendant under oath. Examination for discovery usually takes place in private offices, with only the plaintiffs and defendants, their lawyers, and a reporter present to record a transcript of the testimony. Questioning can be wide-ranging and detailed in order to reveal useful information. Answers given to questions will be available for trial.
2. *Discovery of documents:* Each side can be forced to produce all documents relevant to the litigation. Medical records and nurses' notes may be of particular value.
3. *Independent medical examination of the plaintiff:* This examination is conducted to determine the extent of the plaintiff's injuries. Negligence cannot be charged without proof of damage.
4. *Discovery by interrogatories:* Similar to the examination for discovery, interrogatories involve a series of written questions, which must be answered under oath.

Expert Witnesses

An expert witness is an individual who, because of education, experience, or both, has knowledge that can assist decision makers in establishing whether the nursing care that was provided met the expected standard of practice. Each side usually selects experts to help explain and interpret the evidence as it emerges.

Pretrial Conference

The purpose of the pretrial conference is to identify points of contention, narrow down the issues, and encourage settlement out of court. In some jurisdictions, the pretrial conference may be mandatory. A pretrial conference is presided over by a judge and attended by counsel for the various parties. Most settlements take place without any admission of liability.

Trial

A trial usually occurs several years after the initial statement of claim is filed. Most nursing negligence cases are heard and decided by a judge alone. Damages are usually assessed at trial.

case. The expert witness evaluates the defendant's professional judgements and behaviour under the circumstances being reviewed.

General duty nurses are often legally responsible for meeting the same standards as other general duty nurses in similar settings. However, specialized nurses, such as nurses in a critical care unit or nurses who perform dialysis, are held to standards of care and skill that apply to all professionals in the same specialty. All nurses must know the standards of care that they are expected to meet within their specific specialty

and work setting. Ignorance of the law or of standards of care is not a defence against negligence, nor is being asked by an employer to perform an out-of-scope procedure. The law as written overrules any agency policy or procedure.

Legal Liability Issues in Nursing Practice

Torts

A **tort** is a civil wrong committed against a person or property. Torts may be classified as intentional or unintentional. **Intentional torts** are willful acts that violate another person's rights (Keatings & Smith, 2010). Examples are assault, battery, invasion of privacy, and false imprisonment. Negligence is an example of an unintentional tort.

Intentional Torts

Assault. Assault is conduct (such as a physical or verbal threat) that creates in another person apprehension or fear of imminent harmful or offensive contact. No actual contact is necessary in order for damages for assault to be awarded (Fridman, 2003; Osborne, 2003). Threats by a nurse to give a patient an injection or to restrain a patient for an X-ray procedure when the patient has refused consent constitute assault. The key issues are whether the patient was afraid of being harmed in the situation and whether the patient consented to a procedure. In a lawsuit wherein assault is alleged, the patient's consent would negate the claim of assault against a nurse.

Battery. Battery is any intentional physical contact with a person without that person's consent. The contact can be harmful to the patient and cause an injury, or it can be merely offensive to the patient's personal dignity (Sneiderman et al., 2003). In the example of a nurse's threats to give a patient an injection without the patient's consent, if the nurse actually gives the injection, it is considered battery. Battery could even be life-saving, as in the Ontario case of *Malette v. Shulman* (1990). In that case, the plaintiff was unconscious and bleeding profusely. The physician determined that she needed a life-saving blood transfusion. Before the transfusion, a nurse found a signed card in the plaintiff's purse that identified the patient as a Jehovah's Witness and stated that under no circumstances was she to receive blood. Despite this, the physician chose to administer the blood to preserve the patient's life. The plaintiff survived, recovered from her injuries, and successfully sued the physician for battery (Sneiderman et al., 2003).

In some situations, consent is implied. For example, if a patient gets into a wheelchair or transfers to a stretcher of his or her own volition after being advised that it is time to be taken for an X-ray procedure, the patient has given implied consent to the procedure. A patient has the right to revoke or withdraw consent at any time.

Invasion of Privacy. The tort of invasion of privacy protects the patient's right to be free from unwanted intrusion into his or her private affairs. Patients are entitled to confidential health care. Nursing standards for what constitutes confidential information are based on professional ethics and the common law. The ideals of privacy and sensitivity to the needs and rights of patients who may not choose to have nurses intrude on their lives but who depend on nurses for their care guide the nurse's judgement. The nurse's fiduciary duty requires that confidential information not be shared with anyone else except on a need-to-know basis.

One form of invasion of privacy is the release of a patient's medical information to an unauthorized person, such as a member of the press or the patient's employer. The

information that is contained in a patient's medical record is a confidential communication. It should be shared with health care providers only for the purpose of medical treatment.

A patient's medical record is confidential. The nurse should not disclose the patient's confidential medical information without the patient's consent. For example, a nurse should respect a wish not to inform the patient's family of a terminal illness. Similarly, a nurse should not assume that a patient's spouse or family members know all of the patient's history, particularly with regard to private issues such as mental illness, medications, pregnancy, abortion, birth control, or sexually transmitted infections.

Confidentiality is not an absolute value, however, and in certain circumstances, breaching confidentiality is justifiable. At times, a nurse may be required by law (statutory duty) to breach confidentiality and disclose information to a third party. For example, each province and territory has laws that require health care workers to report suspected child abuse to a local child protection agency. In some jurisdictions, statutes require the notification of the police when there has been a gunshot or a stab wound (*The Gunshot and Stab Wounds Mandatory Reporting Act*, S.M. 2008). Nurses may also be required to release information about a patient when they receive a subpoena (a legal order) to testify in court.

Nurses are under no legal obligation to release confidential information to the police except in rare cases in which the life, safety, or health of the patient or an innocent third party is in jeopardy (such as when a patient tells a nurse that he or she intends to hurt or kill someone). Such a statement should first be reported to the employer's administration or legal counsel before releasing it to the police (Canadian Nurses Protective Society [CNPS], 2008). Other admissions made by a patient to a nurse about past or future criminal activity may not have to be disclosed unless the nurse is compelled to do so by a court of law. The conflict between confidentiality and risk of public harm is not always clear. When a nurse has serious concerns about the welfare of others (e.g., if a patient is infected with human immunodeficiency virus [HIV] and admits to having unsafe sex or donating blood), the nurse should first suggest and strongly encourage the patient to disclose this information. If the patient refuses, the nurse should seek consultation with professional colleagues and supervisors. A careful balancing of the need for privacy and confidentiality of privileged communication would need to be weighed carefully.

Computers and Confidentiality. Most health care facilities use computer systems to maintain patient records. "Computerization in health care raises major legal concerns related to confidentiality of health records because of the potential for unauthorized access and data sharing" (Tapp, 2003). Access to confidential patient information is generally controlled by means of a variety of technological safeguards, including magnetized cards and passwords. It is important that these security devices not be shared with other people and that access cards are used to retrieve files only when warranted. The improper use of a magnetized card and password to seek out confidential information could lead to legal repercussions or disciplinary action.

The use of social media and other forms of electronic communication such as blogs, Facebook, Twitter, and YouTube are used by many as a way to communicate and network. Nurses must be extremely cautious about what information or images they post online, as any information in electronic form can be easily distributed and make its way into the public domain. There is the mistaken belief that deleted information

no longer exists, that privacy controls are totally secure, and that anonymous postings provide protection. Breaches of privacy legislation can lead to disciplinary action by the professional regulatory body, or civil lawsuits alleging defamation (CNPS, 2010). The best way to avoid the inadvertent disclosure of confidential or private information about patients is by maintaining professional boundaries, following employer policies, not posting or sharing any patient-related information online, and not making disparaging comments about your employers or colleagues, as these may be viewed as defamatory (CNPS, 2003).

False Imprisonment. The tort of false imprisonment serves to protect a person's individual liberty and basic rights. Preventing a patient from leaving a health care facility voluntarily may constitute the tort of false imprisonment. The inappropriate or unjustified use of restraints (e.g., by confining a person to an area, or by using physical or chemical restraints) may also be viewed as false imprisonment. Nurses must be aware of their facility's policies and specific legislation in their jurisdiction (e.g., under the *Mental Health and Consequential Amendments Act*, 1998) relating to when and how restraints can be used (CNPS, 2004).

Unintentional Torts

Negligence. When nurses are sued, most often the proceedings against them are for the tort of negligence, also referred to as malpractice (Sneiderman et al., 2003). **Negligence** in nursing is conduct that does not meet a standard of care established by law. No intent is needed for negligence to occur. It is characterized chiefly by inadvertence, thoughtlessness, or inattention. Negligence may involve carelessness, such as not checking an identification bracelet, which results in administration of the wrong medication. However, carelessness is not always the cause of misconduct. If nurses perform a procedure for which they have not been educated and do so carefully but still harm the patient, a claim of negligence can be made. In general, courts define nursing negligence as the failure to use the degree of skill or learning ordinarily used under the same or similar circumstances by members of the nursing profession (Box 8-2).

Nurses can be found liable for negligence if the following criteria are established: (1) The nurse (defendant) owed a duty to the patient (plaintiff); (2) the nurse did not carry out that duty; (3) the patient was injured; and (4) the nurse's failure to carry out the duty caused the injury.

The ability to predict harm (i.e., the foreseeability of risk) is evaluated in negligence cases. The circumstances surrounding the injury are evaluated to determine whether it was likely that

the injury or harm to the patient could have been expected from the care that was or was not provided. The cause of the injury is also investigated through the evaluation of the actual and the nearest causes of the injury. Had it not been for what the nurse did or did not do, could an injury have been prevented?

The case of *Downey v. Rothwell* (1974) is an example of nursing negligence. This case involved a plaintiff who suffered a severe arm injury when she fell off an examining table while under the care of a nurse. The patient, who had a history of epilepsy, informed the nurse that she was about to have a seizure. The nurse left the patient unattended on an examining table while she left the room for a few moments. During this time, the patient had a seizure, fell onto the floor, and broke her arm. The nurse should have anticipated that the patient could have fallen during a seizure and ensured her safety either by moving her to the floor or by putting up guardrails on the examining table. This case involved an undertaking by the nurse to provide care, a reliance by the patient on this nurse, and a foreseeable risk. The nurse was found negligent in this case, and her employers were held vicariously liable. "Vicarious liability is a legal doctrine that applies in situations where the law holds the employer legally responsible for the acts of its employees that occur within the scope and course of their employment" (CNPS, 1998).

In the case of *Granger v. Ottawa General Hospital* (1996), two nurses (a staff nurse and her team leader) were found negligent in the care they provided to a woman in labour. During labour, the plaintiff's fetal heart monitor strip showed deep, persistent, variable decelerations. The staff nurse did not appreciate that these were a sign of fetal distress and did not immediately report these findings to other members of the obstetrical team. The ensuing delay in care resulted in severe and permanent brain injury in the baby, leaving her severely disabled. In this case, the nurses breached their duty to exercise appropriate skill in making an assessment and to communicate the information to the physicians.

Preventing Negligence. The best way for nurses to avoid being negligent is to follow standards of care; give competent health care; insist on appropriate orientation, continuing education, and adequate staffing; communicate with other health care providers; develop a caring rapport with the patient; and document assessments, interventions, and evaluations fully.

The health care record, or "chart," is a permanent record of the nursing process. The courts consult the patient's chart for a chronological record of all aspects of care provided from admission to discharge. "Courts use nursing documentation at trial to reconstruct events, establish times and dates, refresh memories of witnesses and . . . resolve conflicts in testimony" (CNPS, 2007a). As a legal document, it is the most comprehensive record of the care provided. Careful, complete, and thorough documentation is one of the best defences against allegations of negligence or violations of nursing standards (see Chapter 15). The record can show that even in the event of an adverse patient outcome, the nursing care that was provided met the expected standards. An institution has a legal duty to maintain nursing records. Nursing notes contain substantial evidence needed in order to understand the care received by a patient. If records are lost or incomplete, the care is presumed to have been negligent and therefore the cause of the patient's injuries. In addition, incomplete or illegible records undermine the credibility of the health care provider.

In the case of *Kolesar v. Jeffries* (1976), the Supreme Court of Canada addressed the issue of poor record keeping. In that

► BOX 8-2 Common Negligent Acts

- Medication errors that result in injury to patients
- Intravenous therapy errors that result in infiltrations or phlebitis
- Burns caused by equipment, bathing, or spills of hot liquids and foods
- Falls resulting in injury to patients
- Failure to use aseptic technique as required
- Errors in sponge, instrument, or needle counts in surgical cases
- Failure to give a report, or giving an incomplete report, to an incoming shift of health care staff
- Failure to monitor a patient's condition adequately
- Failure to notify a physician of a significant change in a patient's status

case, a patient underwent major spinal surgery and was transferred to a surgical unit, where he was nursed on a Stryker frame. The patient was found dead the following morning. No nursing notes were recorded from 2200 hours the previous evening until 0500 hours, when he was found dead. Although at trial several nurses and nursing assistants testified that they had tended to the patient multiple times throughout the night, the court inferred that “nothing was charted because nothing was done.” One of the nurses was held negligent in this patient’s death.

It is very important for documentation to be accomplished in a timely manner. Any significant changes in the patient’s condition must be reported to the physician and documented in the chart (see Chapter 15). Recording nursing care notes in a notebook and then transferring them to the chart at the end of the shift can be a dangerous practice. If this practice is followed, other health care providers may administer medications or provide care to the patient without up-to-date information. Harm may come to a patient whose record is not accurate and current. Nurses must always follow the particular style of charting adopted by their employer (CNPS, 2007a).

Truthful documentation is also essential. If an error is made in the documentation, it is important to follow the policies and procedures of the institution to correct it. Obliterating or erasing errors may appear to be concealing misconduct and lead to charges of fraud. The credibility of a nurse who goes to court is negatively affected if it appears that the nurse’s initial charting has been changed after an injury has occurred to a patient. This scenario is exemplified in the case of *Meyer v. Gordon* (1981). Nurses did not adequately monitor a woman in labour, and their notes were sloppy and vague. The fetus experienced severe distress, required resuscitation on delivery, and was transferred to another hospital. When a nurse realized that the documentation was deficient, she altered it. However, the original chart had already been photocopied and sent to the second hospital. At trial, it was obvious that the original document had been tampered with. The court held that the nursing staff had been negligent in several ways, and the judge severely condemned the nurse’s tampering with the evidence. The court commented as follows: “My criticism of the defendant hospital is not confined to the lack of care of its nursing staff. The hospital chart contains alterations and additions which compel me to view with suspicion the accuracy of many of the observations which are recorded.”

Nurses should also be familiar with the current nursing literature in their areas of practice. They should know and follow the policies and procedures of the institution in which they work. Nurses should be sensitive to common sources of injury to patients, such as falls and medication errors. Nurses must communicate with the patient, explain the tests and treatment to be performed, document that specific explanations were provided to the patient, and listen to the patient’s concerns about the treatment.

Nurse–patient relationships are very important not only in ensuring quality care but also in minimizing legal risks. Trust develops between a nurse and patient. Patients who believe that the nurses performed their duties correctly and were concerned with their welfare are less likely to initiate a lawsuit against the nurses. Sincere caring for patients is an essential role of the nurse and is an effective risk-management tool. However, caring does not protect nurses completely if negligent practice occurs. When a patient is injured, the

investigation into the incident may implicate the nurses even if the patient feels kindly toward them.

Criminal Liability

Although most nursing liability issues involve private law matters (e.g., torts), the criminal law is also relevant. Canadian nurses have been charged with criminal offences such as assault, administering a noxious substance, and criminal negligence that causes death (a category of manslaughter). The difference between the tort of negligence and criminal negligence charges is the degree to which the act deviated from the standard of a reasonably competent practitioner. For example, in the case of criminal negligence, the courts must prove that the nurse was extremely careless, indicating “wanton or reckless disregard for the lives or safety of other persons” (*Criminal Code*, 1985, Part VIII, Section 219 [1]).

Consent

A signed consent form is required for all routine treatment, procedures such as surgery, some treatment programs such as chemotherapy, and research involving patients. A patient signs general consent forms when admitted to the hospital or other health care facility. The patient or the patient’s representative must sign a special consent or treatment form before each specialized procedure or treatment. “If a person receiving care is clearly incapable of consent, the nurse respects the law on capacity assessment and substitute decision making in his or her jurisdiction” (CNA, 2008, p. 11; see also CNPS, 2009b). Provincial and territorial laws describe what constitutes the legal ability to give consent to medical treatment. Nurses should know the law in their own jurisdiction and be familiar with the policies and procedures of their employing institution with regard to consent.

In general, the following factors must be verified for consent to be legally valid:

- The patient must have the legal and mental capacity to make a treatment decision.
- The consent must be given voluntarily and without coercion.
- The patient must understand the risks and benefits of the procedure or treatment, the risks of not undergoing the procedure or treatment, and any available alternatives to the procedure or treatment.

If a patient is deaf, is illiterate, or does not speak the language of the health care providers, an official interpreter must be available to explain the terms of consent. A family member or acquaintance who is able to speak a patient’s language should not be used to interpret health information except as a last resort. A patient experiencing the effects of a sedative is not able to clearly understand the implications of an invasive procedure. Every effort should be made to assist the patient in making an informed choice.

Nurses must be sensitive to the cultural issues of consent. The nurse must understand the way in which patients and their families communicate and make important decisions. It is essential for nurses to understand the various cultures with which they interact. The cultural beliefs and values of the patient may be very different from those of the nurse. It is important for nurses not to impose their own cultural values on the patient (see Chapter 9).

Informed Consent

“Nurses ensure that nursing care is provided with the person’s informed consent. Nurses recognize and support a capable person’s

right to refuse or withdraw consent for care or treatment at any time" (CNA, 2008, p. 11).

Informed consent is a person's agreement to allow a medical action to happen, such as surgery or an invasive procedure, on the basis of a full disclosure of the likely risks and benefits of the action, alternatives to the action, and the consequences of refusal (Garner & Black, 2009). Informed consent creates a legal duty for the physician or other health care provider to disclose material facts in terms that the patient can reasonably understand in order to make an informed choice (Sneiderman et al., 2003). The explanation should also describe treatment alternatives, as well as the risks involved in all treatment options. Failure to obtain consent in situations other than emergencies may result in a claim of battery. In the absence of informed consent, a patient may bring a lawsuit against the health care provider for negligence, even if the procedure was performed competently. Informed consent requires the provision of adequate information for the patient to form a decision and the documentation of that decision.

The following materials are required for informed consent (Sneiderman et al., 2003):

- A brief, complete explanation of the procedure or treatment
- Names and qualifications of people performing and assisting in the procedure
- A description of any possible harm, including permanent damage or death, that may occur as a result of the procedure
- An explanation of therapeutic alternatives to the proposed procedure or treatment, as well as the risks of doing nothing. Patients also need to be informed of their right to refuse the procedure or treatment without discontinuing other supportive care and of their right to withdraw their consent even after the procedure has begun.

Informed consent is part of the physician–patient relationship. Because nurses do not perform surgery or direct medical procedures, obtaining patients' informed consent is not usually one of nurses' duties. Even though the nurse may assume the responsibility for witnessing the patient's signature on the consent form, the nurse does not legally assume the duty of obtaining informed consent. The nurse's signature witnessing the consent does not mean that the nurse has provided information about risks and alternatives of a particular procedure, only that the patient voluntarily gave consent, that the patient's signature is authentic, and that the patient appears to be competent to give consent (Sneiderman et al., 2003). When nurses provide consent forms for patients to sign, the patients should be asked whether they understand the procedures to which they are consenting. If they deny understanding or if the nurse suspects that they do not understand, the nurse must notify the physician or nursing supervisor. Some consent forms also have a line for the physician to sign after explaining the risks and alternatives to a patient. Such a form is helpful in a court case when a patient alleges that consent was not informed. If a patient refuses treatment, this rejection should also be written, signed, and witnessed.

If a patient participates in an experimental treatment program or submits to use of experimental drugs or treatments, the informed consent form must be even more detailed and stringently regulated. An organization's institutional review board should review the information in the consent form for research involving human subjects. The patient may withdraw from the experiment at any time (see Chapter 7).

Many procedures that nurses perform (e.g., insertion of intravenous or nasogastric tubes) do not require formal written consent; nonetheless, patients' right to give or refuse consent to treatment must be protected. Implied consent to treatment is often involved in nursing procedures. For example, when the nurse approaches the patient with a syringe in hand and the patient rolls over to expose the injection site, consent is implied. If the patient resists the injection either verbally or through actions, the nurse must not proceed with the injection. Forcing or otherwise treating a patient without consent could result in criminal or civil charges of assault and battery. Many advanced practice nurses are now autonomously treating patients. It is therefore likely that formal written consent for nursing procedures will also be expected for the treatment received from advance practice nurse specialists.

Parents are usually the legal guardians of pediatric patients, and, therefore, consent forms for treatment must be signed by parents. If the parents are divorced, the form must be signed by the parent with legal custody. On occasion, a parent or guardian refuses treatment for a child. In those cases, the court may intervene in the child's behalf. The practice of making the child a ward of the court and administering necessary treatment is relatively common in such cases.

The example of 13-year-old Tyrell Dueck from Saskatchewan illustrates such a case. The teenager received a diagnosis of cancer in 1998. He completed part of the chemotherapy treatment when he decided that he did not want more treatment or the recommended amputation of his leg, believing that he had been "cured by God" and that further treatment was unnecessary. His statements were consistent with his family's Christian value system. Following his parents' advice, the boy wished to undergo alternative therapy at a clinic in Mexico. The treating physicians maintained that without further conventional treatment, Tyrell would die within a year. A judge concluded that Tyrell had been given inaccurate information by his father about the benefits and risks of the proposed alternative therapy and, therefore, was unable to make an informed consent or refusal. Thus, the family's wishes to forgo conventional treatment were legally overruled, and the boy's grandparents were to take him for treatments. Before the enforced treatment could be started, however, tests revealed that the cancer had already spread and the treatment would no longer be helpful. The teenager was returned to the care of his parents, and he died a short time later.

In some instances, obtaining informed consent is difficult or simply not possible. If, for example, the patient is unconscious, consent must be obtained from a person legally authorized to give consent on the patient's behalf. Other surrogate decision makers may have legally been delegated this authority through proxy directives or court guardianship procedures. In emergency situations, if it is impossible to obtain consent from the patient or an authorized person, the procedure required to benefit the patient or save the patient's life may be undertaken without liability for failure to obtain consent. In such cases, the law assumes that the patient would wish to be treated. This is referred to as the emergency doctrine.

Patients with mental health problems and frail older adults must also be given the opportunity to give consent. They retain the right to refuse treatment unless a court has legally determined that they are incompetent to decide for themselves.

Nursing Students and Legal Liability

Nursing students must know their own capabilities and competencies and must not perform nursing actions unless

competent to do so. "However, if a student nurse performs a nursing action which is one an RN would perform (e.g. administration of an I.M. [intramuscular] injection), that student will be held to the standard of an RN. Student nurses, like all other nurses, are accountable for their own actions" (Phillips, 2002). In a few reported cases in Canada, nursing students were sued for negligence in their care of patients. A nursing student in Nova Scotia who caused permanent injury in a patient through an improperly administered intramuscular injection was found negligent, and the hospital was found vicariously liable for the student's actions (CNPS, 2007b; *Roberts v. Cape Breton Regional Hospital*, 1997). Thus, nursing students are liable if their actions cause harm to patients. However, if a patient is harmed as a direct result of a nursing student's actions or lack of action, the liability is generally shared by the student, the instructor, the hospital or health care facility, and the university or educational institution. Nursing students should never be assigned to perform tasks for which they are unprepared, and they should be carefully supervised by instructors as they learn new skills. Although nursing students are not considered employees of the hospital, the institution has a responsibility to monitor their acts. Nursing students are expected to ensure that their student status is known to patients and to perform as professional nurses would in providing safe patient care. Faculty members are usually responsible for instructing and observing students, but in some situations, staff nurses serving as preceptors may share these responsibilities. Every nursing school should provide clear definitions of student responsibility, preceptor responsibility, and faculty responsibility (Phillips, 2002).

When students are employed as nursing assistants or nurses' aides when not attending classes, they should not perform tasks that do not appear in a job description for a nurses' aide or assistant. For example, even if a student has learned to administer intramuscular medications in class, this task may not be performed by a nurses' aide. If a staff nurse overseeing the nursing assistant or aide knowingly assigns work without regard for the person's ability to safely conduct the task as defined in the job description, that staff nurse is also liable. If students employed as nurse's aides are requested to perform tasks that they are not prepared to complete safely, this information should be brought to the nursing supervisor's attention so that the needed help can be obtained.

The Web site of the CNPS (<http://www.cnps.ca/> through its members-only-section) is an excellent resource available to nursing students, providing information about legal risks nurses face in practice. However, nursing students are not entitled to receive legal consultation services or financial assistance from the CNPS; these services are provided only for the benefit of eligible registered nurses.

Professional Liability Protection

Most nurses in Canada are employed by publicly funded health care facilities that carry malpractice insurance. These facilities are considered employers and therefore are vicariously liable for negligent acts of their employees as long as the employees were working within the normal scope and course of practice (Keatings & Smith, 2010).

Because of this legal principle, an employer will generally be liable to those who may have suffered damages as a result of the negligence of an employee. Consequently, a patient who considers himself or herself to have been injured by the actions of an employee will often look to the employer for compensation (CNPS, 1998). This legal principle does not apply when

the employee is working outside the normal scope of his or her employment. Accordingly, a nurse who is self-employed or engages in activities that are not related to his or her employment (even if they are undertaken on the employer's premises) is solely liable for his or her own negligence. All nurses should be aware of their employment status as well as the availability and extent of their professional liability coverage.

The CNPS is a nonprofit society established in 1988 to provide legal support and liability protection to nurses. The services of CNPS are available as a benefit of membership in a subscribing provincial or territorial professional association or college. The only two jurisdictions in Canada in which registered nurses are not eligible for CNPS services are British Columbia and Quebec. Registered nurses in British Columbia are covered by their own insurance corporation, and those in Quebec have commercial insurance available through the Order of Nurses of Quebec. CNPS services are otherwise available to nurses in a variety of work settings, including independent practice and volunteer settings. Eligible nurses can obtain confidential assistance from a nurse lawyer by contacting the CNPS toll-free by telephone, Monday to Friday from 0845 to 1630 Eastern Standard Time or Eastern Daylight Time at 1-800-267-3390. A nurse providing emergency assistance at an accident scene may not be covered by an employer's insurance policy because the care given would not fall within the scope of employment. However, some provinces have adopted "Good Samaritan" laws (e.g., Alberta's *Emergency Medical Aid Act*, 2000) that prevent voluntary rescuers from being liable for negligent care provided during a rescue unless it can be proved that they displayed gross negligence. Nurses must be familiar with these laws in their own province or territory.

Abandonment, Assignment, and Contract Issues

Short Staffing. During nursing shortages or periods of staff downsizing, the issue of inadequate staffing may arise. Legal problems may result if the number of nurses is insufficient or if an appropriate mix of staff to provide competent care is lacking. If assigned to care for more patients than is reasonable, nurses should bring this information to the attention of the nursing supervisor. In addition, a written protest such as a workload or staffing report form should be completed to document the nurse's concerns about patient safety. Most provinces and territories have some reporting mechanism in place to document heavy workload or staffing situations. Although such a protest may not relieve nurses of responsibility if a patient suffers injury because of inattention, it would show that they were attempting to act reasonably. Whenever a written protest is made, nurses should keep a copy of this document in their personal files. Most administrators recognize that knowledge of a potential problem shifts some of the responsibility to the institution.

Nurses should not walk out when staffing is inadequate, because charges of abandonment could be made. A nurse who refuses to accept an assignment may be considered insubordinate, and patients would not benefit from having even fewer staff available. It is important to know the institution's policies and procedures and the nursing union's collective agreement on how to handle such circumstances before they arise.

Floating. Nurses are sometimes required to "float" from the area in which they normally practise to other nursing units. Nurses must practise within their level of competence. Nurses should not be floated to areas where they have not been adequately cross-trained. Nurses who float should inform the

nursing supervisor of any lack of experience in caring for the type of patients on the nursing unit. They should also request and be given orientation to the unit. A nursing supervisor can be held liable if a staff nurse is given an assignment he or she cannot safely perform. In one case (*Dessauer v. Memorial General Hospital*, 1981), a nurse in obstetrics was assigned to an emergency room. A patient entered the emergency room, complaining of chest pain. The obstetrical nurse gave the patient too high a dosage of lidocaine, and the patient died after suffering irreversible brain damage and cardiac arrest. The nurse lost the negligence lawsuit.

Physicians' Orders. The physician is responsible for directing medical treatment. Nurses are obligated to follow physicians' orders unless they believe the orders are in error, violate hospital policy, or would harm patients. Therefore, all orders must be assessed, and if an order is found to be erroneous or harmful, further clarification from the physician is necessary. If the physician confirms the order and the nurse still believes it is inappropriate, the supervising nurse should be informed. A nurse should not proceed to perform a physician's order if harm to the patient is foreseeable. The nursing supervisor should be informed of and given a written memorandum detailing the events in chronological order; the nurse's reasons for refusing to carry out the order should also be written, to protect the nurse from disciplinary action. The supervising nurse should help resolve the questionable order. A medical or pharmacy consultant may be called in to help clarify the appropriateness or inappropriateness of the order. A nurse carrying out an inaccurate or inappropriate order may be legally responsible for any harm suffered by the patient.

In a negligence lawsuit against a physician and a hospital, one of the most frequently litigated issues is whether the nurse kept the physician informed of the patient's condition. To inform a physician properly, nurses must perform a competent nursing assessment of the patient to determine the signs and symptoms that are significant in relation to the attending physician's tasks of diagnosis and treatment. Nurses must be certain to document that the physician was notified and to document his or her response, the nurse's follow-up, and the patient's response. For example, nurses noticed that a patient with a cast on his leg was experiencing poor circulation in his foot. The nurses recorded these changes but did not notify the physician. Gangrene subsequently developed in the patient, and an amputation was required. The hospital, physician, and nursing staff were all charged with negligence.

The physician should write all orders, including "do not resuscitate" (DNR) orders, which many physicians are reluctant to write out because they fear legal repercussions for criminal neglect or failure to act. The nurse must make sure that orders are transcribed correctly. Verbal orders are not recommended because they increase the possibilities for error. If a verbal order is necessary (e.g., during an emergency), it should be written and signed by the physician as soon as possible, usually within 24 hours. The nurse should be familiar with the institution's policy and procedures regarding verbal orders.

Dispensing Advice Over the Phone. Providing advice over the telephone is a high-risk activity because diagnosing over the phone is extremely difficult. The nurse is legally accountable for advice given over the phone. The most common allegations of negligence in this area are provision of inadequate advice, improper referrals, and failure to refer (CNPS, 2009a). It is essential that nurses precisely follow institutional

guidelines and policies and thoroughly document each call to avoid serious repercussions for all parties.

Contracts and Employment Agreements. In Canada, most nurses belong to unions or associations that engage in collective bargaining on behalf of a group. The collective agreements between employers and union members are written contracts that set out the conditions of employment (e.g., salary, hours of work, benefits, layoffs, and termination). Many laws, including labour laws, apply to nurses. For example, laws outline eligibility for and details of workers' compensation and maternity benefits. It is important for nurses to understand the employment laws in the province or territory where they work.

By accepting a job, a nurse enters into an agreement with an employer. The nurse is expected to perform professional duties competently, adhering to the policies and procedures of the institution. In return, the employer pays for the nursing services and ensures that facilities and equipment are adequate for safe care.

Legal Issues in Nursing Practice

Abortion

In the 1988 case of *R. v. Morgentaler*, the Supreme Court of Canada ruled that the *Criminal Code* (1985) regulations on legal access to abortion were unconstitutional. The *Criminal Code* had required a woman seeking abortion to secure the approval of a hospital-based committee before the procedure could be performed. By rejecting the *Criminal Code* provisions, the Supreme Court in effect referred the abortion issue to Parliament, but Parliament has not rewritten a criminal law policy on abortion. Abortion is thus unregulated by law, which is tantamount to its legalization. However, the legal entitlement to abortion does not mean abortion services are readily available. Because health care facilities are not obliged to offer abortions, many do not do so. Thus, access remains a continuing issue.

Drug Regulations and Nurses

Canadian law closely regulates the administration of drugs. Two federal acts control the manufacture, distribution, and sale of food, drugs, cosmetics, and therapeutic devices in Canada: the *Food and Drugs Act* (1985) and the *Controlled Drugs and Substances Act* (1996). The *Food and Drugs Act* lists the drugs that can be sold only by prescription (e.g., antibiotics) and drugs that are subject to stringent controls (e.g., barbiturates, amphetamines). The distribution of these drugs requires specific handling and record keeping. The *Controlled Drugs and Substances Act* controls the manufacture, distribution, and sale of narcotics (e.g., morphine, codeine). However, it also regulates other drugs that are controlled in the same manner as narcotics, such as cocaine and marijuana. Most institutions have policies about medication administration and record keeping, especially for controlled drugs and narcotics. Nurses must be aware of their employer's policies.

Nurses are not legally entitled to prescribe drugs. However, in several jurisdictions, nurse practitioners may prescribe certain non-narcotic drugs specific to their area of practice.

The administration of medications in accordance with a physician's prescription is a basic nursing responsibility. A competent nurse is expected to know the purpose and effect of any drug administered, as well as potential side effects and contraindications. It is also a nurse's responsibility to question any physician's orders that may be incorrect or unsafe. A nurse

who follows a physician's order that is unclear or incorrect may be found negligent, disciplined, or dismissed by the employer, or investigated by the professional regulatory body (CNPS, 2007a).

Communicable Diseases

The care of people with communicable conditions such as HIV infection, acquired immunodeficiency syndrome (AIDS), hepatitis, or severe acute respiratory syndrome (SARS) or during a possible influenza pandemic has legal implications for nurses. Health care workers are at risk for exposure to communicable diseases because of the nature of their work. Despite the best attempts to protect oneself against communicable diseases through the proper and consistent use of protective gear (e.g., latex gloves or masks), accidental needle-stick injuries or life-threatening illnesses such as SARS can occur. Nurses have an ethical and legal obligation to provide care to all assigned patients, and employers have an obligation to provide their employees with necessary protective gear. However, there may be "some circumstances in which it is acceptable for a nurse to withdraw from care provision or to refuse to provide care" (College of Registered Nurses of British Columbia [CRNBC], 2007, p. 1; see also College of Registered Nurses of Nova Scotia, 2006). "Unreasonable burden is a concept raised in relation to duty to provide care and withdrawing from providing or refusing to provide care. An unreasonable burden may exist when a nurse's ability to provide safe care and meet professional standards of practice is compromised by unreasonable expectations, lack of resources, or ongoing threats to personal wellbeing" (CNA, 2008; see also CRNBC, 2007, p. 1).

In all cases involving privacy, confidentiality, and disclosure, the rights of the patients with a communicable disease must be balanced with the rights of the public or of health care providers. Both civil and criminal liability can result if private information is disclosed without authorization. Nurses must understand the reporting laws in the province or territory in which they practise. Courts can order disclosure of the records of patients with AIDS in situations that are not addressed by a statute, even without the patient's consent. Whenever information about a patient is requested by any third parties, including insurance companies or employers, nurses must obtain a signed release from the patient before releasing confidential information. Not every health care provider who comes in contact with a patient has a need to know the patient's HIV status. Confidential information must be protected.

The courts have upheld the employer's right to fire a nurse who refuses to care for a patient with AIDS. Nurses who flatly refuse to care for HIV infected patients or possibly a patient with SARS may be reprimanded or fired for insubordination. According to the CNA's (2008) *Code of Ethics for Registered Nurses*, nurses must not discriminate in the provision of nursing care on the basis of factors such as a person's sexual orientation, health status, or lifestyle (p. 13). One limitation outlined in the code regarding a nurse's right to refuse care to a patient is that nurses are not obligated to comply with a patient's wishes when those wishes are contrary to the law (e.g., assisting the patient to commit suicide). If the care requested is contrary to the nurse's personal values, such as assisting with an abortion, the nurse must provide appropriate care until alternative care arrangements are arranged.

Nurses must be concerned with balancing the right to protect themselves with protection of the patient's rights. Both are afforded protection against discrimination and protection

of privacy by human rights legislation. Most current legal cases involving nurses and communicable diseases are related to the protection needed for nurses as employees. Strict compliance with standard precautions and routine practices and the use of transmission-based precautions (e.g., against airborne or droplet transmission) for patients known or suspected of having other serious illnesses is the nurse's wisest strategy (see Chapter 32).

Death and Dying

Many legal issues surround the event of death, including a basic definition of when a person is considered dead. The only province that has a statutory definition of death is Manitoba, which defines it as "the irreversible cessation of all brain function" (*Vital Statistics Act*, 1987). However, this "brain death" definition has become standard medical practice across Canada. Until the 1960s, death was defined as the irreversible cessation of cardiopulmonary function. However, two developments at that time necessitated a shift to consideration of the brain: (1) the emergence of artificial life-support devices that could maintain cardiopulmonary functioning in a brain-dead person and (2) the emergence of organ transplantation. Death had to be redefined so that organs could be donated.

Ethical and legal questions are raised by the related issues of euthanasia and assisted suicide. **Euthanasia** is an act undertaken by one person with the motive of relieving another person's suffering and the knowledge that the act will end the life of that person (Downie, 2004). In Canada, euthanasia is illegal. It is legally irrelevant whether the patient has consented to the act because according to Section 14 of the *Criminal Code* (1985), "no person can consent to have death inflicted on him." Furthermore, according to Section 241 of the *Criminal Code*, it is an offence to "aid a person to commit suicide, whether suicide ensues or not."

On the other hand, the law draws a distinction between "killing" and "letting die." Euthanasia and assisted suicide are considered "killing." Withholding or withdrawing life-prolonging treatment is considered "letting die." The disease process causes the patient to die a natural death. Thus, a mentally competent patient has the legal right to refuse life-prolonging treatment. If, for example, such a patient requests that a ventilator be disconnected, understanding that she will die as a result, her wishes must be honoured in accordance with the principle of "no treatment without consent."

In the case of *Nancy B. v. Hôtel-Dieu de Québec* (1992), a young, mentally competent patient who was totally and permanently paralyzed by a neurological disease had twice asked that her ventilator be disconnected. After the second refusal, she sought a court order to enforce her will. The order was granted by the Quebec Superior Court, which ruled that as a mentally competent patient, she could not be treated without consent. Also, even if a patient has not asked for the termination of life-prolonging treatment (either directly or by way of an advance directive), physicians are still allowed, after consultation with family members, to terminate such treatment when it no longer offers any reasonable hope of benefit to the person. When patients reject life-prolonging treatment, the nurse focuses on the goal of caring versus curing.

Right-to-die legislation is currently being challenged in Canada for the first time since 1993 when the Supreme Court of Canada ruled 5 to 4 against giving Sue Rodriguez the right to die by assisted suicide. The Victoria woman, who had amyotrophic lateral sclerosis (ALS), later ended her life by suicide.

On November 14, 2011, the Supreme Court of British Columbia began hearing arguments in a constitutional challenge to the *Criminal Code* sanctions against physician-assisted suicide. The trial, known as *Carter v. Attorney General of Canada*, has been brought forward by the B. C. Civil Liberties Association and a group of individuals, including Gloria Taylor, who, like Sue Rodriguez, is afflicted with ALS (*Carter v. Canada [Attorney General]*, 2011 BCSC 1371). Nurses must be aware of changes that take place as laws continue to evolve.

Advance Directives and Health Care Surrogates

The **advance directive** is a mechanism enabling a mentally competent person to plan for a time when he or she may lack the mental capacity to make medical treatment decisions. It takes effect only when the person becomes incompetent to speak for himself or herself. The advance directive is a more sophisticated concept than that of the living will, although the two terms are often confused. A **living will** is a document in which the person makes an anticipatory refusal of life-prolonging measures during a future state of mental incompetence. An advance directive, in contrast, is not restricted to the rejection of life-support measures; its focus is on treatment preferences, which may include both requests for and refusals of treatment. The advance directive assumes two forms: the instructional directive (in which the maker of the document spells out specific directions for governing care, in more detail than is generally found in the living will), and the proxy directive (in which the person appoints someone as a health care agent to make treatment decisions on his or her behalf). Legislation in British Columbia, Alberta, Saskatchewan, Manitoba, Ontario, Prince Edward Island, Newfoundland and Labrador, and the Yukon gives full legal effect to both kinds of directives; the proxy directive is also recognized in Quebec and Nova Scotia. Even in provinces and territories that do not recognize an instructional directive, nothing prohibits a physician from following a directive.

If nurses know about the existence of a health care directive, they are required to follow it. Nurses are also required to follow the wishes of a validly appointed proxy (assuming these instructions are legal). A proxy has the right to receive all medical information concerning the patient's condition and proposed plan of care. Failure to comply with a proxy's directions could result in charges of battery.

If a physician ignores the advance directive, the nurse must bring the advance directive to the physician's attention and document that he or she did so, along with the physician's response to this information. The nurse should also notify the nursing supervisor, who can then give direction regarding institutional policies and guidelines for such circumstances.

The psychiatric advance directive is a new type of advance directive. An individual with mental health problems completes this type of directive during periods of mental stability and competence. The directive outlines how the patient wishes to be treated in the future if the underlying mental illness causes him or her to lose decision-making capacity. For example, it may specify preferences for and against certain interventions (e.g., electroconvulsive therapy) or medications. The psychiatric advance directive can also designate a surrogate decision maker to act on the person's behalf in the event of an incapacitating mental health crisis.

Organ Donation

Legally competent people are free to donate their bodies or organs for medical use. Every province and territory has

human tissue legislation that provides for both the *inter vivos* (live donor) and postmortem (cadaveric) donation of tissues and organs. For example, a mentally competent adult is allowed to donate a kidney, a lobe of the liver, or bone marrow. Statutes provide that adults may consent to organ donation after death. If the deceased has left no direction for postmortem donation, consent may be obtained from the person's family. In two provinces—Manitoba and Nova Scotia—the statutes contain "required request" provisions that take effect when a deceased person did not consent to organ removal but is considered a good donor candidate. In such an event, the physician is legally obliged to seek permission from the family. In many hospitals, a nurse transplantation coordinator performs this function.

Mental Health Issues

Treating patients with mental health problems raises legal and ethical issues. Provincial mental health legislation such as the *Mental Health and Consequential Amendments Act* (1998) provides direction for health care providers, protects patient autonomy, and recognizes that some individuals with severe mental health problems may lack the ability to appreciate the consequences of their health condition.

A patient can be admitted to a psychiatric unit involuntarily or on a voluntary basis. Patients admitted on a voluntary basis should be treated no differently than any other patient. They have the right to refuse treatment and the right to discharge themselves from hospital. However, provincial or territorial mental health legislation provides that if the patient may cause harm to self or others, police officers (or other authorized parties) may bring the patient to a health care facility for examination and treatment without the patient's consent (Sneiderman et al., 2003).

Potentially suicidal patients may be admitted to psychiatric units. If the patient's history and medical records indicate suicidal tendencies, the patient must be kept under supervision. A lawsuit may result if a patient attempts suicide within the hospital. The allegations in the lawsuits would be that the institution failed to provide adequate supervision or safeguard the facilities. Documentation of precautions against suicide is essential.

Public Health Issues

It is important that nurses, especially those employed in community health settings, understand the public health laws. Public health acts, which have been enacted in all provinces and territories, are directed toward the prevention, treatment, and suppression of communicable disease (Sneiderman et al., 2003). Community health nurses have the legal responsibility to follow the laws enacted to protect the public health. These laws may include reporting suspected abuse and neglect, such as child abuse, elder abuse, or domestic violence; reporting communicable diseases; and reporting of other health-related issues enacted to protect the public's health.

Some provinces (e.g., Ontario and New Brunswick) have legislation that requires proof of immunization for school entry. In these provinces, however, exceptions are permitted on medical or religious grounds and for reasons of conscience (Health Canada, 1997). Although a signed consent form is not required for an immunization, nurses are advised to obtain some documentation (evidence) that they discussed the risks and benefits with the parent or legal guardian. Nurses should be aware of their employer guidelines for documentation.

Every province and territory has child abuse legislation that requires health care providers, such as nurses, to report witnessed or suspected child abuse or neglect directly to child protection agencies. To encourage reports of suspected cases, the laws offer legal immunity for the reporter if the report is made in good faith. Health care providers who do not report suspected child abuse or neglect may be held liable for civil or criminal action. Several provinces and territories also have laws that require health care workers to report witnessed or suspected abuse of patients within facilities (e.g., *The Protection of Persons in Care Act*, 2000, in Manitoba). These reports must be made directly to a public authority. Even if public reporting is not required, nurses should report all suspicions of patient abuse to their nursing supervisors. It is essential for nurses to know their provincial or territorial laws and employer policies regarding the reporting of abuse.

Risk Management

Risk management is a system of ensuring appropriate nursing care by identifying potential hazards and eliminating them before harm occurs (Guido, 2006). The steps involved in risk management include identifying possible risks, analyzing them, acting to reduce them, and evaluating the steps taken.

One tool used in risk management is the **incident report**, or **adverse occurrence report**. When a patient is harmed or endangered by incorrect care, such as a drug error, a nurse completes an incident report (see Chapter 15). Such reports are analyzed to determine how future problems can be avoided. For example, if incident reports show that drug errors commonly involve a new intravenous pump, the risk manager must ensure that staff members have been properly trained in its use. In-service education may be all that is necessary to prevent future errors.

The underlying rationale for quality assurance in risk-management programs is the highest possible quality of care. Some insurance companies and medical and nursing organizations require the use of quality assurance and risk-management procedures. Quality care is the responsibility of both the employer and the individual provider.

Risk management requires sufficient documentation. The nurse's documentation can be the evidence of what actually was done for a patient and can serve as proof that the nurse acted reasonably and safely. Documentation should be thorough, accurate, and performed in a timely manner. When a lawsuit is being evaluated, the nurse's notes are very often the first record to be reviewed by the plaintiff's counsel. If the nurse's credibility is questioned because of these documents, the risk of greater liability exists for the nurse. The nurse's notes are risk-management and quality assurance tools for the employer and the individual nurse.

Professional Involvement

Nurses must be involved in their professional organizations and on committees that define the standards of care for nursing practice. If current laws, rules and regulations, or policies under which nurses must practise do not reflect reality, nurses must become involved as advocates to see that the scope of nursing practice is accurately defined. Nurses must be willing to represent the nursing profession's perspective, as well as the patient's perspective in the community. Nurses can be powerful and effective when the organizing focus is the protection and welfare of the public entrusted to their care.

❖ KEY CONCEPTS

- With increased emphasis on patient rights, nurses in practice today must understand their legal obligations and responsibilities to patients.
- The civil law system is concerned with the protection of a person's private rights, and the criminal law system deals with the rights of individuals and society.
- A nurse can be found liable for negligence if the following criteria are established: the nurse (defendant) owed a duty of care to the patient (plaintiff), the nurse did not carry out that duty, the patient was injured, and the nurse's failure to carry out the duty caused the patient's injury.
- Patients are entitled to confidential health care and freedom from unauthorized release of information.
- Under the law, practising nurses must follow standards of care, which originate in nursing practice acts and regulations, the guidelines of professional organizations, and the written policies and procedures of employing institutions.
- Nurses are responsible for confirming that the patient has given informed consent to any surgery or other medical procedure before the procedure is performed.
- Nurses are responsible for performing all procedures correctly and exercising professional judgement as they carry out physicians' orders.
- Nurses are obligated to follow physicians' orders unless they believe the orders are in error or could be detrimental to patients.
- Staffing standards determine the ratio of nurses to patients, and if the nurse is required to care for more patients than is reasonable, a formal protest should be made to the nursing administration.
- Legal issues involving death include documenting all events surrounding the death and treating the deceased patient's remains with dignity.
- A competent adult can legally give consent to donate specific organs, and nurses may serve as witnesses to this decision.
- All nurses should know the laws that apply to their area of practice.
- Depending on provincial statutes, nurses are required to report suspected child abuse and certain communicable diseases.
- Nurses are patient advocates and ensure quality of care through risk management and lobbying for safe nursing practice standards.
- Nurses must file incident reports in all situations when someone could or did get hurt.

❖ CRITICAL THINKING EXERCISES

1. Nurse Rossi and Nurse Kao are getting on an elevator to go down to the cafeteria. Several visitors are present in the elevator, as are hospital personnel. Nurse Rossi and Nurse Kao are talking about a patient who is in the intensive care unit who has just tested positive for HIV infection. They identify the patient as "the man in Room 14B." One of the visitors on the elevator who overhears this information is a woman who is engaged to the patient in Room 14B.
 - a. Have Nurse Rossi and Nurse Kao breached a patient's right to confidential health care?
 - b. Would the patient in Room 14B have any legal cause of action against the nurses?
 - c. Even though the patient's fiancée may have a right to know the HIV status of her future husband, do the nurses have any duty to disclose confidential information to the fiancée?

2. While transporting a patient down the hall on a stretcher, Nurse Reyes stops to chat with an orderly. The side rails on the stretcher are down, and while Nurse Reyes has her back to the stretcher, the patient rolls over, falls off the stretcher, and fractures his hip. In a lawsuit by the patient against Nurse Reyes, what must the patient establish to prove negligence against the nurse?

✦ REVIEW QUESTIONS

- The nursing practice acts are an example of
 - Statute law
 - Common law
 - Public law
 - Criminal law
- Treating a patient without his or her consent is considered
 - Battery
 - Negligence
 - Implied consent
 - Expressed consent
- The nurse restrains a patient without the patient's permission and without a physician's order. The nurse may be guilty of
 - Assault
 - False imprisonment
 - Invasion of privacy
 - Neglect
- The situation in which a confused patient fell out of bed because side rails were not used when they were ordered is an example of which type of liability?
 - False imprisonment
 - Assault
 - Battery
 - Negligence
- What should you do if you think the patient does not understand the procedure for which he or she is being asked to give consent?
 - Do not be concerned if the consent is already signed.
 - Notify the physician or nursing supervisor.
 - Send the patient for the procedure and discuss it afterward.
 - Ask a family member to give consent.
- When a patient is harmed as a result of a nursing student's actions or lack of action, the liability is generally held by
 - The student
 - The student's instructor or preceptor
 - The hospital or health care facility
 - All of the above
- When the nurse stops to help in an emergency at the scene of an accident, if the injured party files suit and the nurse's employing institution's insurance does not cover the nurse, the nurse would probably be covered by
 - The nurse's automobile insurance
 - The nurse's homeowner's insurance
 - The Patient Care Partnership, which may grant immunity from suit if the injured party consents
 - The Good Samaritan laws, which grant immunity from suit if no gross negligence is involved

- The nurse is obligated to follow a physician's order unless
 - The order is a verbal order
 - The physician's order is illegible
 - The order has not been transcribed
 - The order is in error, violates hospital policy, or would be detrimental to the patient
- If a third party (e.g., insurance company of employer) requests health information on a patient, the nurse must
 - Provide the information
 - Refuse to provide the information
 - Obtain a signed release by the patient before releasing the information
 - Contact the patient's family or lawyer
- When is it acceptable for a nurse to post information about a patient on a social networking site?
 - If the patient's name is not provided
 - If the posting is done anonymously
 - If the site has privacy controls
 - It is inappropriate to post patient information online

✦ RECOMMENDED WEB SITES

Canadian Nurses Association—Provincial/Territorial Members: http://www.cnaaicc.ca/CNA/about/members/provincial/default_e.aspx

This CNA site offers up-to-date Weblinks and contact information for all provincial and territorial nursing colleges and associations.

The Canadian Nurses Protective Society: <http://www.cnps.ca>
The Canadian Nurses Protective Society (CNPS) helps nurses manage their professional legal risks by offering legal support and liability protection. The members-only section of the Web site (the user name is the acronym of your professional association or college, and the password is "assist") provides information on a variety of legal topics affecting Canadian nursing practice.

Department of Justice Canada: <http://laws.justice.gc.ca/en/>
This site provides links to consolidated statutes, including the *Criminal Code* (1985) of Canada.

The Health Law Institute of Dalhousie University: The End of Life Project: http://as01.ucis.dal.ca/dhli/cmp_welcome/default.cfm

This site contains information about the Canadian law pertaining to various aspects of end-of-life care, including advance directives and withholding of life-sustaining treatment.

Rationales for the Review Questions appear at the end of the book.

Global Health, Culture, and Diversity

Written by Barbara J. Astle, RN, PhD, Sylvia S. Barton, RN, PhD, Leanne Johnson, RN, MN, and Judy Mill, RN, PhD

objectives

Mastery of content in this chapter will enable you to

- Describe the key terms listed.
- Differentiate between global health, international health, and public health in the context of professional nursing.
- Describe the concepts of global citizenship and the professional roles of nursing in a global world.
- Describe the diversity of the Canadian population.
- Define key cultural concepts related to health, illness, and diversity.
- Describe the historical development of the concept of culture, cultural competence, and cultural safety in relation to nursing practice.
- Analyze components of cultural assessment to understand the values, beliefs, and practices critical in the nursing care of people experiencing cultural transitions.
- Apply selected components of cultural assessment to particular cultural groups and populations.
- Examine nursing responsibilities that underpin relational practice and the way in which relational inquiry can enhance professional nursing practice.
- Apply research findings to the provision of culturally competent care with considerations for cultural safety and relational practice.
- Apply cultural assessment components to the Aboriginal peoples of Canada.

Global Health

As we progress into the twenty-first century, it is increasingly apparent that nurses have a key role to play in examining global health challenges, developing solutions, and implementing change. As Austin (2004), a nurse ethicist, reminds us, "In this area of globalization, our moral space is changing and we need to develop an openness, an attentiveness to persons and other living things outside our immediate geographical community" (p. 352). Nursing's responsibility for global health is consistent with our history in advocating for social justice and is critical to ensure that global health inequities are minimized or eliminated. In order to contribute to global health, nurses need to understand key concepts related to global health, global citizenship, health equity, cultural safety, and diversity.

Global health refers to “the optimal well-being of all humans from the individual and collective perspective...” (Canadian Nurses Association [CNA], 2009, p. 1). According to Koplan and colleagues (2009), global health encompasses prevention, treatment, and care, while focusing on the improvement of health for all and health equity. These authors argue that in addition to transnational health issues, global health is concerned with domestic health disparities. In addition they suggest that “the *global* in global health refers to the scope of problems, not their location” (p. 1994). For instance, poverty in inner-city neighbourhoods, limited access to health care in rural communities, and high rates of malaria in sub-Saharan African children are all examples of global health issues. In order to achieve global health, interdisciplinary collaboration and authentic partnerships between high-income and low-and/or middle-income countries (LMIC) are required to develop effective solutions for complex health issues (Koplan et al., 2009). Benatar (2005) argues that moral imagination, or the ability to imagine what it is like to be in another person’s situation, is necessary to make progress toward global health.

Koplan and colleagues (2009) suggest that global health overlaps with concepts derived from the disciplines of **public health** and **international health**. Each of these domains shares several common characteristics: a population-based and preventative focus, work with marginalized populations, a focus on multidisciplinary and interdisciplinary approaches, acknowledgement that health is a public good, an emphasis on systems and structures, and participation with key stakeholders. Table 9-1 compares the similarities and differences of each of the three domains.

Health Equity

Health equity is a concept that is fundamental to understanding and achieving global health. Health inequalities or health disparities refer to differences in health status among different population groups (Health Disparities Task Group, 2004). *Health inequities*, on the other hand, refer to “differences in health that are not only unnecessary and avoidable but, in addition, are considered unfair and unjust” (Whitehead, 1992,

p. 430). Braveman and Gruskin (2003) suggest that **health equity** refers to the “absence of systematic disparities in health (and its key social determinants) that are systematically associated with social advantage/disadvantage” (p. 256). Health inequity puts disadvantaged groups at further disadvantage, and poverty is often the root cause. The inability of all persons living with HIV in sub-Saharan Africa to access care and treatment is an example of a health equity issue.

Braveman and colleagues (2011) caution that health inequity implies a judgement about the causality of differences and suggest that measuring health inequities relies on quantifying health disparities. The term *health equity* is a normative concept that reflects the value of social justice (Braveman et al., 2011; Reutter & Kushner, 2010). Thus, health equity is a critical and necessary element to achieve health for all, because of the underlying value that health is a human right and the implicit goal to eliminate differences in health is unfair.

Reutter and Kushner (2010) argue that nursing has a strong and clear mandate to reduce health inequities among individuals, families, and communities, as well as to take action on the social conditions that contribute to health inequities. These authors suggest that nursing must provide sensitive, empowering care to individuals experiencing health inequities and, at the same time, participate in policy analysis and advocacy to reduce inequities.

Global Citizenship

Global citizenship is a concept that has been discussed for many years and has been advocated by a variety of disciplines, including law, community health, education, epidemiology, and nursing. Mill and colleagues (2010) argue that global citizenship is a critical role and responsibility for professional nurses. **Global citizenship** refers to our responsibilities as citizens to not only engage in our local, national, and international community, but to act upon social injustices and inequities (Oxfam, 1997). A **global citizen** incorporates not only an *inward* personal awareness and commitment to global issues, but also *outward* actions on local or global issues (Hanson, 2010). Byers (2005) suggests that “global citizenship empowers individuals

► **TABLE 9-1** Comparison of Global, International, and Public Health

	Global Health	International Health	Public Health
Geographical Reach	Focuses on issues that directly or indirectly affect health but that can transcend national boundaries	Focuses on health issues of countries other than one’s own, especially those of low- and middle-income countries	Focuses on issues that affect the health of the population of a particular community or country
Level of cooperation	Development and implementation of solutions often requires global cooperation	Development and implementation of solutions often requires bi-national cooperation	Development and implementation of solutions does not usually require global cooperation
Individuals or populations	Embraces both prevention in populations or clinical care of individuals	Embraces both prevention in populations or clinical care of individuals	Mainly focuses on prevention programs for populations
Access to health	Health equity among nations and for all people is a major objective	Seeks to help people of other nations	Health equity within a nation or community is a major objective
Range of disciplines	Highly interdisciplinary and multidisciplinary within and beyond health sciences	Embraces a few disciplines but has not emphasized multidisciplinary	Encourages multidisciplinary approaches, particularly within health sciences and with social sciences

Source: Koplan, J. P., Bond, T. C., Merson, M. H., Reddy, K. S., Rodriguez, M. H., Sewankambo, N. K., Wasserheit, J. N. (2009). Towards a common definition of global health. *The Lancet*, 373, 1994.

to participate in the decisions concerning their lives, including the political, economic, social, cultural and environmental conditions in which they live" (p. 37). The common thread in global citizenship is our *interconnectedness*, and the acknowledgement that the local and global are connected, with one perspective not privileged over the other (Mill et al., 2010). According to Oxfam (1997), the characteristics of a global citizen include but are not limited to awareness of the wider world; respecting and valuing diversity; understanding the economic, political, social, cultural, technological, and environmental influences; contributing to the community at a local and global level; striving toward sustainability in the world; taking responsibility for our own actions; and acting on social injustice. Nurses have an extensive history of working with the marginalized in society and in advocating for social justice (CNA, 2010b). The roots of social responsibility in nursing have been traced to pioneers such as Florence Nightingale, Margaret Sanger, Lavinia Dock, and Lillian Wald (Coss, 1989; Duncan et al., 1999; Kelley et al., 2008; Smith, 2000).

Cultural Diversity

Canada has always been a multicultural nation. At the time of Confederation, more than 50 Aboriginal groups—each with its own language and culture—lived in Canada, in addition to the founding British and French settlers and other settlers migrating primarily from European countries. Canada is well known as a country that embraces diversity, relying heavily on immigration for population growth (Adams, 2007). As a result, the societal landscape changes continuously, integrating people from many ethnic groups who have migrated to this country and formed a cultural mosaic that is uniquely Canadian (Statistics Canada, 2007a, 2008b).

The ethnocultural profile of Canada is continually evolving. More than 200 ethnic origins were reported by the total population in Canada in the 2011 census. After Canadian, the other most frequently reported origins in 2006, either alone or with other origins, were English, French, Scottish, Irish, German, Italian, Chinese, North American Indian, and Ukrainian. According to the 2006 census, visible minorities accounted for 16.2% of Canada's total population, up from 13.4% in 2001 and 11.2% in 1996 (Statistics Canada, 2008b; Figure 9-1). Between 2001 and 2006, the visible minority population increased at a much faster rate than did the total population (Statistics Canada, 2008b). For the purposes of the 2011 census, the *Employment Equity Act* defines visible minorities as persons, other than Aboriginal peoples, who are non-Caucasian in race or nonwhite in colour (Statistics Canada, 2008b). The increase in the visible minority population was largely attributable to the high proportion of newcomers who belonged to visible minorities.

Figure 9-2 shows the most common visible minority groups in Canada. The three largest visible minority groups are South Asians, Chinese, and Blacks. South Asians surpassed Chinese as the largest visible minority group in 2006 (Statistics Canada, 2008b). Both the populations of South Asians and Chinese were well over 1 million. In Canada in 2006, South Asians represented 24.9% of all visible minorities and 4.0% of the total population, Chinese accounted for about 24.0% of the visible minority population and 3.9% of the total population, and Blacks accounted for 15.5% of the visible minority population and 2.5% of the total population (Statistics Canada, 2008b).

Figure 9-1 Number and share of visible minority persons in Canada, 1981–2008. **Source:** Adapted from Statistics Canada. (2008). *Canada's ethnocultural mosaic, 2006 census*. Retrieved from <http://www12.statcan.ca/english/census06/analysis/ethnorigin/index.cfm>.

Figure 9-2 The composition of Canada's visible minority population, 2006. **Source:** Adapted from Statistics Canada (2008). *Canada's ethnocultural mosaic, 2006 census*. Retrieved from <http://www12.statcan.ca/english/census06/analysis/ethnorigin/index.cfm>.

Immigration continues to play a pivotal role in shaping Canada's ethnocultural profile (Statistics Canada, 2007a). According to the 2006 census, approximately 19.8% (one per five) of Canada's total population were born outside of the country, reaching the highest level in 75 years (Statistics Canada, 2007a). For the purposes of the 2006 census, a *foreign-born population* is also known as an *immigrant population* and is

defined as persons who are, or who have been, landed immigrants in Canada (Statistics Canada, 2007a). Canada ranks second only to Australia as the country with the highest proportion of foreign-born citizens. In addition, Canada receives more immigrants per capita than does the United States (Statistics Canada, 2007a). The largest groups of immigrants to Canada are from Asian and Middle Eastern countries; this fact has remained virtually unchanged since the 2001 census. In contrast, during 1971, only 12.1% of immigrants to Canada were born in Asian and Middle Eastern countries, and 61.6% were born in Europe. By 2006, 58.3% of recent immigrants were Asian and only 16.1% were European. Immigration has now outpaced the natural birth rate of the country, as revealed by Statistics Canada (2007a) between 2001 and 2006. Statistics Canada reports that Canada's foreign-born population increased by 13.3%, which was four times higher than the increase in the Canadian-born population of 3.3%. Thus, immigrants and refugees come to Canada from many places, representing more than 200 ethnocultural groups across the country (Statistics Canada, 2007a).

Two other significant aspects of Canada's cultural mosaic are the Aboriginal population and the population of French ancestry. In the 2006 census, more than 2 million people, representing 3.8% of the total population, reported having at least some Aboriginal ancestry (Statistics Canada, 2008a). Aboriginal Canadians may also be considered an Indigenous group of which there are more than 370 million indigenous people globally (Nettleton et al., 2007; United Nations, 2008). **Indigenous peoples** are referred to as "indigenous, tribal, aboriginal or minority groups or peoples" (Stephens et al., 2005, p. 11). In the 2006 census, population by knowledge of official language by province and territory revealed that citizens who spoke only French totalled more than 4 million, of a total of more than 31 million Canadians (Statistics Canada, 2007b). In response to Canada's ethnocultural mosaic, nurses require an understanding of difference in order to perceive, critically, the diversity influences that shape healing, well-being, and caring patterns (Racher & Annis, 2012). Historically, a nurse who pioneered a more transcultural view of nursing was Lyle Morrison Creelman (Box 9-1).

Understanding Cultural Concepts

Clarification of key concepts related to culture and ethnicity are crucial to understanding their complexity. The Canadian Nurses Association (CNA, 2010a) describes **culture** broadly as shared patterns of learned values and behaviours that are transmitted over time and that distinguish the members of one group from another. Culture can include language, ethnicity, spiritual and religious beliefs, socioeconomic class, gender, sexual orientation, age, group history, geographic origin, and education, as well as childhood and life experiences. According to the CNA's (2008a, 2008b) *Code of Ethics*, "When providing care, nurses do not discriminate on the basis of a person's race, ethnicity, culture, political and spiritual beliefs, social or marital status, gender, sexual orientation, age, health status, place of origin, lifestyle, mental or physical ability or socioeconomic status or any other attribute" (p. 14).

Culture has both **visible** (easily seen) and **invisible** (less observable) components. The invisible value and belief system of a particular culture is the major driving force behind visible practices. Although a Sikh man may be easily identified by visible symbols (uncut hair with wooden comb, beard, turban,

BOX 9-1

Milestones in Canadian Nursing History

Lyle Morrison Creelman, 1908-2007

Born in Upper Stewiack, Nova Scotia, Lyle Morrison Creelman, arguably Canada's foremost international nurse, was a visionary and collaborative leader whose career exemplifies the exciting possibilities of the nurse/scholar to lead change. She passionately articulated the importance of nursing's contribution to global health, as she fought to introduce improved nursing standards and a more modern vision of community-based public health nursing worldwide.

A 1936 graduate of the University of British Columbia in public health nursing and recipient of a Rockefeller Foundation fellowship to Teachers College, Columbia University, in 1939, she was appointed director of nursing in 1941 of a groundbreaking internationally funded project to integrate all public health services in greater Vancouver communities. She launched her international career with the United Nations Relief and Rehabilitation Administration in 1944. As chief nurse of the British Occupied Zone of Germany, she orchestrated nursing services for millions of displaced persons awaiting repatriation or resettlement. After her return home in 1947, Creelman co-authored with Dr. J.H. Baillie a landmark study that set new directions for public health practice in Canada for years to come. In 1949, she joined the World Health Organization (WHO) and subsequently served as the organization's chief nursing officer (CNO) from 1954 to 1968.

Primary health care, social justice and caring remained core values underpinning her philosophy of nursing. As CNO, Creelman pioneered a more transcultural view of international nursing that valued culturally sensitive, sustainable, and affordable nursing services. Rather than imposing Western models from the top down, she stressed that nursing services, education, and research must be developed at the grassroots level and tailored to the local socioeconomic context. To achieve these goals, she was an early proponent of shifting from expensive, curative medical approaches to practices that emphasize disease prevention and health promotion as a global strategy. Lyle Creelman spent her career helping nurses communicate more effectively and engage in community and global partnerships to gain a directing voice in the struggle for a more equitable distribution of health care resources nationally and globally. Her voice still resonates today in the 1978 Declaration of Alma-Ata and the 2003 Florence Nightingale Initiative for Global Health.

steel bracelet, and steel dagger), for example, the meanings and beliefs associated with these artifacts are not readily apparent. These artifacts symbolize a devotee's allegiance to the pillars of Sikhism, and removal of them without expressed consent of the individual or his family may be considered sacrilegious, violating the ethnoreligious identity of the person.

In Canada, the prevalent cultures are anglophones and francophones with origins from Western Europe. **Subcultures** such as the Ukrainian and Acadian cultures represent various ethnic, religious, and other groups with distinct characteristics. **Ethnicity** refers to groups whose members share a social and cultural heritage. Members of ethnic groups, for example, may share common values, language, history, physical characteristics, and geographical space. The most important characteristic of an ethnic group is that its members feel a sense of common identity. People may declare their ethnic identity, for instance, as Scottish, Vietnamese, or Colombian. A term that is usually contrasted with ethnicity is **race**, which is limited to the

common biological attributes shared by a group, such as skin colour (Spector, 2012).

Cultural pluralism is a perspective that “promotes respect for the right of others to have different beliefs, values, behaviours, and ways of life” (Racher & Annis, 2012, p. 159). **Cultural relativism** “fosters awareness and appreciation of cultural differences, rejects assumptions of superiority of one’s culture and adverts ethnocentrism” (Racher & Annis, 2012, p. 159). In any intercultural encounter, nurses “are challenged to be open and responsive to cultural differences, while respecting, protecting, and promoting the rights and well-being of those people and groups with whom they work” (Racher & Annis, 2012, p. 160). As nurses, for example, we need to be aware that Canada is a major immigrant-receiving country: preliminary numbers reveal that 280,636 new permanent residents immigrated to Canada from 169 countries in 2010 (Citizenship and Immigration Canada, 2011). As Ogilvie (2011) suggests, such diversity requires nurses to seek out knowledge on what cultural competence is, what cultural safety is, and what the connection is between the two. Community health nurses, for example, may need to be knowledgeable about parenting in newcomer families in order to develop a portrait of the health and well-being of these families (Wilkinson et al., 2010).

The processes of enculturation and acculturation facilitate cultural learning. Socialization into one’s primary culture during childhood is known as **enculturation**. The process of adapting to and adopting characteristics of a new culture is **acculturation** (Cowan & Norman, 2006). Acculturation outcomes may result in varying degrees of affiliation with the mainstream culture (Spector, 2012). **Assimilation** is a process whereby a minority group gradually adopts the attitudes and customs of the mainstream culture (Srivastava, 2007a). In relation to acculturation, the notion of integration may be viewed as an example of an adaptive process of acculturation.

In contrast to assimilation, **multiculturalism**, regarded as a fundamental characteristic of Canadian society, is a process whereby “many cultures co-exist in society and maintain their cultural differences. Multiculturalism also refers to the public policy of managing cultural diversity in a multi-ethnic society, emphasizing tolerance and respect for cultural diversity” (Srivastava, 2007b, p. 328). In 1971, Canada became the first country in the world to officially adopt a multiculturalism policy. Since then, various laws have been passed to protect and promote the rights of minorities in Canada (Box 9-2). As expressed in the spirit of the multicultural policy, citizens are able to retain their unique ethnocultural traditions within a Canadian context.

Cultural Conflicts

Culture provides the context for valuing, evaluating, and categorizing life experiences. As values, morals, and norms are transmitted from one generation to another, members of ethnic groups may display **ethnocentrism**, a tendency to view their own way of life as more valuable than others’. Health care practitioners who do not understand cultural differences often resort to **cultural imposition**, in which they use their own values and ways of life as the absolute guides in providing services to patients and interpreting their behaviours. Hence, if a nurse believes that pain is to be borne quietly as a demonstration of strong moral character, that nurse may be annoyed by a patient’s insistence on being given pain medication and, in denying the patient’s discomfort, may exacerbate the patient’s pain.

BOX 9-2

Legislation Recognizing Diversity in Canada

Official Languages Act (1969; Updated 1988)

This Act recognizes English and French equally as Canada’s official languages. The 1988 amendment to this Act outlines the obligations of Canadian federal institutions to be committed to promoting full recognition and use of both English and French in Canadian society, as well as supporting the development of the anglophone and francophone communities across the country.

Canadian Constitution Act (1982)

This Act replaced the *British North America Act* as Canada’s Constitution, outlining how Canada governs and structures its society. It also recognizes the Aboriginal peoples of Canada as Indians (Status and Non-Status), Inuit, and Métis.

Canadian Charter of Rights and Freedoms (1982)

Written into the *Canadian Constitution* in 1982, this charter is a statement of the basic human rights and freedoms of all Canadians.

Canadian Multiculturalism Act (1988)

In recognition of Canada’s cultural diversity, this Act enshrines the enhancement and preservation of multiculturalism in Canada.

Ethnocentrism is the root of stereotypes, biases, and prejudices against other people perceived to be different from the valued group. You need to avoid **stereotypes**, which are generalizations about any particular group that prevent further assessment of unique characteristics. When a person acts on his or her prejudices, **discrimination**—treating people unfairly on the basis of their group membership—occurs. **Racism** involves specific actions and an attitude whereby one group exerts power over others on the basis of either skin colour or racial heritage; its effects are to marginalize and oppress some people and to endow others with privileges (Srivastava, 2007a). Often, people do not realize that they are displaying prejudice or discrimination; such displays may be simply negative or fearful reactions to cultural differences (see Chapter 10 for a description of Ethel Johns’s work on racism).

Historical Development of the Concept of Culture

It is important to review historically the emergence of trans-cultural nursing in relation to shifts in thinking about the provision of culturally competent care and cultural safety. Framed primarily within the Canadian context, this history is also best discussed in terms of culturally appropriate nursing practice and education. The importance of being culturally sensitive and aware of a diverse society has been acknowledged by nurses and continues to evolve. Nurses became aware of the conceptual limitations of culture, partly by studying the complexities of race (Ramsden, 2002). Through a critical cultural analysis of the significance of power relations and structural constraints on health and health care, nurses are conceptualizing new ways to provide culturally competent and culturally safe care (Anderson et al., 2003; Baker, 2007; Browne & Varcoe, 2006; Brown et al., 2009; Gustafson, 2007; Racine, 2009; Ramsden, 2002; Smith et al., 2006). A critical

historical view of transcultural nursing, cultural competence, and cultural safety is important for understanding the strengths and limitations of these approaches in nursing practice and education (Gustafson, 2005). Increasingly, nurse scholars are questioning whether the health needs of ethnic cultural groups are being equitably met (Anderson et al., 2003; Baker, 2007; Smith et al., 2006). Equity may be considered one of the prerequisites and conditions for health. Mill and colleagues (2005) revealed how “nurses can provide valuable support to the realization of the goal of global health by becoming informed advocates and integrating these concepts, in nursing practice, education and research” (p. 22). Furthermore, in a second article (Ogilvie et al., 2005), the same scholars explained how “nurses can play a pivotal role by becoming informed advocates, challenging their organizations to incorporate a global health mandate and exercising their rights as citizens to influence policy” (p. 25).

The discipline of anthropology and seminal work by Leininger (2002b) relative to cultural nursing have both highly influenced the establishment of a theoretical foundation of transcultural nursing (Glittenberg, 2004). Leininger defined **transcultural nursing** as a comparative study of cultures, an understanding of similarities (culture universal) and differences (culture specific) across human groups in order to provide meaningful and beneficial delivery of health care (Leininger, 2002b). According to Leininger, the goals of transcultural nursing are to provide *culturally congruent* and *culturally competent care*.

Culturally congruent care is “the use of sensitive, creative, and meaningful care practices to fit with the general values, beliefs, and lifeways of clients” (Leininger & McFarland, 2002, p. 12). In other words, you need to determine how to provide care that does not conflict with patients’ valued life patterns and sets of meanings, which may be distinct from your own (Leininger, 2002a).

Leininger and McFarland (2002) defined **culturally competent care** as “the explicit use of culturally based care and health knowledge in sensitive, creative, and meaningful ways to fit the general lifeways and needs of individuals or groups for beneficial and meaningful health and well-being or to help them face illness, disabilities, or death” (p. 84). To provide culturally competent care, you must bridge cultural gaps in care, work with cultural differences, and enable patients and families to receive meaningful care. You need to exhibit specific ability, knowledge, sensitivity, openness, and flexibility toward the appreciation of cultural difference (Suh, 2004). You are then able to develop effective and meaningful interventions that promote optimal health for patients, families, and communities.

The work of Leininger in promoting culturally competent care with people from diverse cultures has been the prevailing model identified in the nursing literature. It has been used as a guide in nursing curricula and practice policies in North America for several decades. In addition, other scholars have developed models of cultural competency in which they have expanded Leininger’s work. Davidhizar and Giger (1998; also Giger, 2013) developed a **transcultural assessment model** with a focus on cultural competency that is used in nursing practice. The underlying premise of their model is that each person is culturally unique and should be assessed according to six cultural phenomena: communication, space, social organization, time, environmental control, and biological variations. The model suggests that these phenomena are apparent in all

Figure 9-3 The process of cultural competence. **Source:** Campinha-Bacote, J. (2002). The process of cultural competence in the delivery of health-care services: A model of care. *Journal of Transcultural Nursing*, 13(3), 181. cultural groups, but their application to practice settings varies. Giger and Davidhizar’s transcultural assessment model offers a means for you to assess patients’ unique health care needs, including their specific cultural health practices.

Campinha-Bacote (2002) further defined cultural competence as an ongoing process, whereby you continuously strive to work within the patient’s cultural context. As a result, you develop cultural competence rather than possess it. This ongoing process involves integrating cultural awareness, knowledge, skill, encounters, and desire, as depicted in Figure 9-3. *Cultural awareness* is insight into one’s own background, and it involves an in-depth self-examination to recognize biases, prejudices, and assumptions about other people. *Cultural knowledge* is knowing about the patient’s culture. It involves learning about diverse groups, including their values, health beliefs, care practices, and world views. As a nurse assigned to a female Egyptian-Canadian patient, for example, you decide to seek information about the Egyptian culture. Upon learning that female modesty and gender-congruent care are valued in the culture, you encourage the patient’s female relatives to assist with her hygiene needs. *Cultural skills* include assessment of social, cultural, and biophysical factors that influence patient care. *Cultural encounters* involve engaging in cross-cultural interactions that can teach about other cultures. *Cultural desire* is the motivation and commitment to learn from other people, to accept the role as learner, to be accepting of cultural differences, and to build relationships based on cultural similarities.

Narayanasamy (2002), a nurse scholar in Britain, also developed a framework for cultural competence: the ACCESS model (A for assessment; C for communication; C for cultural negotiation and compromise; E for establishing respect and rapport; S for sensitivity; and S for safety). The focus of this model is on developing cross-cultural communication, cultural negotiations, diversity, and celebrations, and on fostering cultural safety (Narayanasamy & White, 2005).

In Canada, the CNA (2010a) advocates in its position statement that culturally competent care can and should be practised in all clinical settings. The “underlying values for cultural competence are inclusivity, respect, valuing differences, equity and commitment” (Registered Nurses’ Association of Ontario, 2007, p. 19). Cultural competence is viewed as a key concept in the application of knowledge, skill, attitudes, and personal attributes by nurses in the provision of appropriate care and services in relation to the cultural characteristics of patients. A nurse practising in this way, for instance, would hold the belief of valuing diversity, be interested in and seek out knowledge as appropriate about cultural mores and traditions from diverse patients being served, and be sensitive to these while caring for the cultural diverse person. Although nurses are responsible for providing culturally competent care, nursing regulatory bodies, professional associations, educational institutions, governments, health service agencies, and accreditation organizations share the responsibility of supporting culturally competent care. You are in a position to build partnerships with other health care providers, patients, and funding agencies in order to establish culturally diverse practices that optimize patients’ health outcomes.

The provision of culturally competent care has been promoted since the 1960s. Only since 2000, however, have Canadian nurse scholars begun to question the limitations of such an approach (Anderson et al., 2003; Kirkham, 2003) and to examine, critically, the concept of **cultural safety** as another approach to providing care to diverse groups, in contrast to the conceptual notion of transcultural nursing (Ramsden, 2002). The College of Registered Nurses of British Columbia’s (2006) profile of newly graduated registered nurse practice focuses on the therapeutic caring and culturally safe relationships between patients and health care team members. The cultural safety literature is framed within a critical social theory and postcolonial framework. The concept of cultural safety evolved over a number of years in New Zealand, as nurses tried to identify a way in which health care providers could more effectively address the inequity in the health status of Maori people. This was combined with an analysis of the historical, political, social, and economic situations influencing the health of Maori people (Ramsden, 2002). Cultural safety involves considering the redistribution of power and resources in a relationship. The notion “is based on the premise that the term ‘culture’ is used in its broadest sense to apply to any person or group of people who may differ from the nurse/midwife because of socio-economic status, age, gender, sexual orientation, ethnic origin, migrant/refugee status, religious belief or disability” (Ramsden, 2002, Chapter 8, p. 3). In contrast to transcultural nursing, the term *culture* refers to ethnicity. As a result, the philosophy of cultural care has shifted from a notion of cultural sensitivity underpinning the provisions of care irrespective of culture to one of cultural safety with the recognition of power imbalances, the understanding of the nature of interpersonal relationships, and the awareness of institutional discrimination (Baker, 2007; Browne & Fiske, 2001; Brown et al., 2009; CNA, 2010a; Racine, 2009) (Box 9-3). Thus, understanding and providing culturally competent and safe care have the potential to make a difference to the health of many culturally diverse groups, especially Canada’s Aboriginal population of First Nations, Inuit, and Métis peoples.

Ramsden (2002) articulated that *cultural awareness* and *cultural sensitivity* are separate concepts and that those terms are not interchangeable with *cultural safety*. Achieving cultural

BOX 9-3 RESEARCH HIGHLIGHT

Globalization and the Cultural Safety of an Immigrant Muslim Community

Research Focus

The social health of Muslims who reside in smaller areas of Canada is not clearly understood by health care providers. The concept of cultural safety has been used in studies of both Aboriginal peoples and immigrants to understand the health of Aboriginal peoples and immigrants in a large metropolitan centre, but the dichotomy between culturally safe and unsafe groups was found to be blurred. To further understand the concept of cultural safety, Baker (2007) focused on the social health of a small immigrant community of Muslims in a relatively homogeneous region of Canada after the terrorist attacks in the United States on September 11, 2001 (“9/11”).

Research Abstract

Many Muslims living in North America and Western Europe were negatively affected by the events of 9/11. A qualitative approach based on the constructivist paradigm was used to guide the study, and 26 in-depth interviews were conducted with Muslims (10 women and 16 men) of Middle Eastern, Pakistani, or Indian origin. The participants resided in the province of New Brunswick, Canada, between 2002 and 2003. Data collection and analysis were conducted simultaneously. Steps of unitizing, categorizing, and pattern seeking were used to dissect the interviews until saturation was obtained. Many participants reported that after 9/11, their Islamic faith and experiences of being Muslim suddenly became significant to society at large. The research findings revealed that these participants talked about a sudden transition from cultural safety to cultural risk after 9/11. Their positive experiences of cultural safety included invisibility as a minority and a sense of social integration in the community. Cultural risk was found to stem from intensive international media attention that highlighted their now-visible minority status.

Evidence-Informed Practice

In this study, the findings indicated that globalization does not necessarily blur the distinction between culturally safe and culturally unsafe groups. Cultural risk may be generated by outside forces rather than by long-term inequities in relationships between groups within the community, which did not necessarily originate in historical events. Such findings suggest that you need to think about cultural safety in Muslims within the context of globalization. In addition, you should be cognizant about the cultural safety of your practice when providing care to members of socially disadvantaged cultural groups and how this may influence the health care received.

safety is a step-wise progression from cultural awareness through cultural sensitivity to cultural safety (Figure 9-4). The outcome of cultural safety is that safe care, defined as such by patients who receive the care, is provided. According to Ramsden (2002), **cultural sensitivity** “alerts students to the legitimacy of difference and begins a process of self-exploration as the powerful bearers of their own life experience and realities which can have an impact on others” (Ramsden, 2002, Chapter 8, p. 4). **Cultural awareness** “is a beginning step toward understanding that there is difference. Many people undergo courses designed to sensitize them to formal ritual

Figure 9-4 Steps toward achieving cultural safety in nursing practice. **Source:** Adapted from Ramsden, I. M. (2002). *Cultural safety and nursing education in Aotearoa and TeWaipounamu* (unpublished PhD thesis). Wellington, New Zealand: Victoria University of Wellington. Retrieved from <http://culturalsafety.massey.ac.nz>.

and practice rather than the emotional, social, economic and political context in which people exist" (Ramsden, 2002, Chapter 8, p. 4). A strategy for achieving cultural awareness is to conduct a self-assessment in order to reflect on your biases and feelings. A set of questions for personal reflection is suggested for this purpose in Box 9-4. Another strategy is to observe nurses who are considered to be exemplary relational practitioners and to notice the particular qualities or characteristics they display when handling the cultural aspects of relationships (Box 9-5).

With regard to achieving cultural safety in nursing practice, Ramsden stated that "the skill for nurses does not lie in knowing the customs or even the health related beliefs of ethno-specific groups. The step before that lies in professional acquisition of trust. Rather than the nurse determining what is culturally safe, it is consumers or patients who decide whether they feel safe with the care that has been given, that trust has been established, and that difference between the patient, the nurse and the institutions that underpin them, can then be identified and negotiated" (Ramsden, 2002, Chapter 8, p. 4), as depicted in Figure 9-4.

Cultural Assessment

A comprehensive cultural assessment is the basis for providing culturally competent care. A cultural assessment, combined with critical thinking skills, provides the knowledge necessary for transcultural nursing care (Andrews & Boyle, 2012). Cultural assessment is a systematic and comprehensive examination of the cultural care values, beliefs, and practices of individuals, families, and communities. The goal of cultural assessment is to generate from the patients themselves significant information that enables culturally congruent care (Leininger & McFarland, 2002). Several models of cultural

► BOX 9-4 Questions for Reflection and Building Awareness in Nursing

Personal Self-Awareness

What is my ethnic background? How does my knowledge of my ethnicity affect my identity? What meaning do I ascribe to my ethnic origins? How have they shaped who I am today? What cultural groups do I belong to? What are the rules, customs, and rituals that have been passed on to me and that I will pass on to the next generation of my family? How were these passed on to me, and what meaning do I give to them now? How do the rules and customs passed on to me inform how I engage with others?

Professional Self-Awareness

In my work, how do I relate to others of different cultures? What taken-for-granted assumptions am I prepared to make in the name of efficiency and time constraints? What stereotypes do I hold? How do these beliefs influence my practice? How do I maintain an attitude of cultural attunement in my work with groups and organizations? How do I bridge the differences between ethnic backgrounds in my work? What action might I take to improve my cultural attunement?

Organizational Awareness

What are the values and principles of my organization for working cross-culturally? How does my organization reflect behaviours, attitudes, policies, and structures when working cross-culturally? How does my organization value diversity, manage the dynamics of difference, acquire and institutionalize cultural knowledge, and adapt to diversity and the cultural contexts of the communities it serves?

Community Awareness

How do the dynamics of the community, such as racial tensions, enter into my work with community groups and organizations? When does difference make a difference? How does this community influence feelings of belonging among its residents? What actions do we take to be inclusive? How do we celebrate and honour cultural diversity? What do we need to do differently to be more inclusive and generate feelings of belonging among residents from all cultures?

Honouring culture and diversity in community practice. In A. R. Vollman, E. T. Anderson, & J. McFarlane (Eds.), *Canadian community as partner: Theory & multidisciplinary practice* (3rd ed., p. 172). Philadelphia, PA: Lippincott Williams & Wilkins.

assessment exist, each involving different levels of skill and knowledge. Leininger's Sunrise Model (Leininger & McFarland, 2002), depicted in Figure 9-5, demonstrates the inclusiveness of culture in everyday life and helps explain why cultural assessment must be comprehensive. According to the Sunrise Model, cultural care values, beliefs, and practices are embedded in the cultural and social structural dimensions of society, which include environmental contexts, language, and ethnohistory (i.e., significant historical experiences of a particular group). For older adults, for example, the experience of the Great Depression has sometimes resulted in a tendency to be frugal. You must encourage patients to share stories

► BOX 9-5 An Exemplary Relational Practitioner

1. *Identify* someone whom you would say is “good at relationships.” Why did you identify that person? What qualities or characteristics stand out?
2. Now *identify* someone who is a nurse and is good at relationships. Think of someone with whom you have worked—perhaps a fellow student, a colleague, an instructor. What makes this person good at relationships? How is this person perceived by his or her colleagues?
3. *Compare notes* with someone else. Talk to someone who has thought about this question, or talk to someone who knows the person or people you have identified. Do you both value similar attributes and qualities?

Source: Doane, G. H., & Varcoe, C. (2005). *Family nursing as relational inquiry: Developing health-promoting practice* (p. 192). Philadelphia, PA: Lippincott Williams & Wilkins.

about their lives that reveal how they think and the cultural lifestyle they embrace. Leininger’s model differentiates folk care, which is caring as defined by the people, from the health care professions, which is based on the scientific, biomedical system of care.

Whichever assessment model is used, you begin cultural assessment by knowing population demographic changes in the practice setting. You anticipate the patient populations that use their own methods of care and gain some knowledge about their cultures before they come to the clinical setting. Background knowledge about a culture assists you in conducting a focused assessment when time is limited. Demographic information can be gathered from the local and regional census data, as well as from the patients themselves. Demographic information might include the distribution of ethnic groups, education, occupations, and incidence of the most common illnesses. Comprehensive cultural assessment requires skill

Figure 9-5 Leininger’s culture care theory and Sunrise Model. **Source:** Leininger, M. M., & McFarland, M. R. (2002). *Transcultural nursing: Concepts, theories, research and practice* (3rd ed., p. 80). New York: McGraw-Hill.

and time; hence, preparation and anticipation of needs are important.

A challenge in cultural assessment is the lack of ability to assess multiple perspectives of patients and to interpret the information elicited. It helps to use open-ended questions (e.g., "What do you think caused your illness?"), focused questions (e.g., "Have you had this problem before?"), and contrast questions (e.g., "How different is this problem from the one you had previously?"). The aim is to encourage patients to describe values, beliefs, and practices that are significant to their care, which may be taken for granted unless otherwise revealed. Culturally oriented questions are by nature broad and require a lot of description. Table 9-2 provides a list of guiding questions (a **cultural assessment guide**) that focuses on social and cultural dimensions of assessment.

According to some health care providers, the idea of a specific cultural assessment model or tool further marginalizes those from particular cultures by placing emphasis on the difficulties with difference. It is important to remember that the many questions used in the cultural assessment tool and culturally sensitive communication tool are just as suitable for Canadians within the dominant group, such as white Anglo-Saxons. The question to be raised is this: Why not just have one assessment tool for everyone? For instance, everyone might be asked what their preference for touch is or how they like to be addressed.

Selected Components of Cultural Assessment

Cultural assessment is important in the total care of any patient. Over time, you will learn various skills needed to gather an accurate and comprehensive assessment. The following sections describe certain components of cultural assessment that provide information that can be useful in planning and providing nursing care. You may use the following information as a starting point to assess the similarities and differences of patients and families. However, it is better not to assume that because any two patients come from the same region or country, they share similar values, beliefs, attitudes, and experiences. Other elements to consider are the social determinants of health: early childhood development, education, employment and working conditions, food security, health care services, housing shortages, income, social safety nets, social exclusion, and unemployment and employment security (Raphael, 2008).

Ethnohistory

Knowledge of a patient's country of origin and its history and ecological contexts is significant to health care. Haitian immigrants, for example, have linguistic and communication patterns distinct from those of Jamaicans, even though both groups come from the Caribbean region and may have a common history of oppression. Differences can be traced to their colonial history and intermingling with the local indigenous people. Cultural characteristics of Hindu immigrants from Jamaica are different from those of Hindu immigrants from India because of the cultural contexts of the different regions. The nutritional, communication, and health patterns of Hindus from Jamaica may be more similar to those of African Jamaicans than to those of South Asian Hindus. When caring for a Hindu patient of Indian descent who grew up in Jamaica, you may expect that he or she will interact more like a Jamaican, although he or she may look South Indian.

You should be aware that people immigrate to another country for various reasons and have different motivations for doing so. Refugees may be relocated without having chosen their new location, in contrast to immigrants who are able to choose where they live. Refugees tend to experience greater dislocation and deprivation than do immigrants who enter Canada with specialized skills and education and who have the option to return to their homeland. Age at immigration may determine the level of acculturation: younger immigrants acculturate faster than do their older counterparts. Similarities shared by an immigrant group with the prevailing culture in society are strong predictors of how easily the members of that group adjust. Although acculturation and length of residence in the new country are related, outcomes may be affected by other factors, such as education, racial characteristics, and familiarity with language and religion. You may ask patients about the circumstances that brought them to Canada and how they believe they are adjusting. You need to understand, for instance, any problems the patient may have (such as becoming comfortable with routines or the language used to arrange medical appointments), in order to make reasonable and appropriate adjustments to care.

You should also be aware that newly arrived immigrants and refugees, depending on the geographic location from which they originate, are vulnerable to a variety of health conditions, including tuberculosis, hepatitis B, anemia, dental caries, intestinal parasites, nutritional deficiencies, incomplete immunization, and mental and emotional concerns such as depression and post-traumatic stress disorder (Kemp, 2004). New immigrants and refugees also frequently experience language barriers, social isolation, separation from family, loss and grief, and a lack of information about available resources. It is important that you explore the historical and sociopolitical background of a patient with regard to the specific immigrant community; this knowledge assists you in formulating a plan of care (Lo & Pottinger, 2007). Therefore, you should be aware of, and advocate for, primary health care programs in the community for these vulnerable patients.

Social Organization

Cultural groups consist of units of organization delineated by kinship, status hierarchy, and appropriate roles for their members. Nurses need to consider all options when determining a patient's next of kin. This is especially relevant to new immigrants and refugees, who may have relocated without intact families. The status of a patient within the social hierarchy is generally linked with qualities such as age and gender, as well as with achievements such as education and position. The mainstream culture in Canada emphasizes achievement as the determinant of status, whereas other cultures may give higher priority to age and gender. In many Asian and African cultures, for instance, the eldest son is next in line after his father with regard to authority. A Korean mother may be subject to the authority of her oldest son in the absence of her husband. Older adults occupy higher status in some societies, so that grandparents may impose their decisions regarding the care of grandchildren over the decisions of their married children. You may be required to facilitate and support the negotiations for determining who has the responsibility for family decision making. Think of a nurse you have observed who acted as negotiator, advocator, and facilitator in a situation in which family roles needed to be clarified.

► **TABLE 9-2 Cultural Assessment Guide**

Subject	Suggested Questions	Subject	Suggested Questions
Cultural identity/ ancestry/heritage Ethnohistory	Where were you born? Where were your parents born? How long have you or your parents resided in this country? What is your ethnic background or ancestry? How strongly are you influenced by your culture? Why did you leave your homeland?	Language and communication	What language(s) do you speak at home? What language(s) are you most comfortable speaking? In what language(s) can you read and write? How do you want us to talk to you? How should we address you, or what should we call you? What kinds of communication upset or offend you? What words would you use to describe how you feel? Do you need an interpreter? Would you prefer a female or male interpreter?
Social organization	Who lives with you? Whom do you consider members of your family? Where do you live? Where do other members of your family live? How do you contact them? How often do you have contact with your family members? Who makes the decisions for you or your family? Whom do you go to outside of your family for support? What do you expect your family members to do for you? How different are your expectations of them now from your expectations at other times? What expectations do you have of your family members who are male, female, old, or young?	Religion/spirituality	What is your religion? Who is your religious or spiritual leader? Do you want to be in touch with your religious leader? How do we contact your spiritual leader? What are some of the things we need to do within your religion? How do you practise your religion? Do you follow specific dietary practices? What do you do to keep yourself well? What do you do to show someone you care?
Socioeconomic status	What do you do for a living? What did you do back in your homeland? Where did you go to school? What level did you finish in school? How different is your life here from your life back in your homeland? Do you have a primary health care provider? What other health care providers have you seen?	Caring beliefs and practices	How does your family or you take care of sick family members? Which caregivers do you seek when you are sick? How do you decide when to go to a caregiver and which one to go to? How different is what we do from what your family does for you when you are sick?
Biocultural ecology and health risks	What is your purpose for coming here? What caused your problem? Have you had this problem before? Does this problem affect your life and your family? How? Do other members of your family have this kind of problem? How do you treat this problem at home? Whom do you go to for this kind of problem? What other plans do you have for dealing with this problem? What do you think we should do for you? What other problems do you have? Have these problems occurred with any other member of your family?	Experience with professional health care	Are we doing what you think we should be doing for you? How should we give you care? Since you came to this country, have you had contact with doctors or hospitals? How do you compare your past health care experience with those of the present? What were some of the problems that you encountered? How were they resolved? What were the positive experiences you had? What type of health care provider do you prefer? Why? If you have a choice, what changes do you wish to see?

Role expectations of family members may be defined by culture and differentiated by gender. Devout female Muslims, for example, tend to be caregivers, and male Muslims tend to be providers and major decision makers. Some Muslim women may insist on staying at the bedside of an unwell child, in-laws,

or husband, but the assumption that she can be relied on to make decisions independently as the primary caregiver may be unrealistic. The social hierarchy of the family needs to be determined as soon as possible, in order to avoid offending patients and their families.

Socioeconomic Status, Biocultural Ecology, and Health Risks

The identification of health risks related to sociocultural and biological history can be assessed on admission of patients. Distinct health risks can be attributed to the ecological context of the culture. Immigrants from the region near the Nile River, for example, are generally predisposed to parasitic infestations endemic to that region. Immigrants from developing countries with poor sanitary conditions and water supply may have infections such as hepatitis that they can pass on to others. In addition, biological variations exist between people from different ethnic groups. As a result, some groups have greater risk of developing certain health conditions. Some genetic disorders, for example, are linked with specific groups, such as Tay-Sachs disease among Ashkenazi Jews and malignant hypertension among Black Canadians.

Language and Communication

Distinct linguistic and communication patterns are associated with different cultural groups. These patterns reflect the core cultural values of a society. In Western cultures that uphold individualism, assertive communication is valued because it demonstrates autonomy and self-determination. People are expected to say what they mean and to mean what they say. In collectivistic cultures, communication is shaped by the context of relationships among participants. Group harmony is the priority, so that participants interact on the basis of their expected positions and relationships within the social hierarchy. People are more likely to remain respectful and show deference to older adults or family leaders, even though they may disagree on an issue. Among Asian cultures, for example, face-saving communication promotes harmony by indirect, ambiguous communication and by conflict avoidance. Messages spoken may have little to do with their meanings. Saying no to a superior or older person may not be permitted; hence, an affirmative response of a subordinate may mean only “I heard you,” rather than full agreement.

In cultural groups with distinct linear hierarchy, conflict is negotiated between people with the same level of position or authority. Identifying and working with family members of an established hierarchy may prevent miscommunication. In cultures with highly differentiated gender roles, some patients may place more value on the advice of a male nurse than on that of a female nurse. By recognizing and working within a particular cultural context, the nurse can become more effective in achieving appropriate outcomes.

Nonverbal communication is also shaped by culture. Culture influences the distance between participants in an interaction, the extent of touching, the degree of eye contact, and how much private information the patient shares. Patients use less distance when speaking to trusted affiliates and persons of the same gender, age, and social position. Members of many ethnic groups tend to speak their own dialect with each other in order to feel ease and to secure privacy. To minimize the distance when communicating with patients, you need to consider taking up a relational approach to cultural nursing that greatly enhances the ability to know and respond to people (Hartrick Doane & Varcoe, 2005). A relational approach to nursing allows you not only to connect across differences but also to recognize cultural similarities and differences more intently. Such an approach provides opportunities “to attend to issues of meaning, experience, race, history, culture, health, and sociopolitical systems. In addition, as we

relationally honour and attend to such differences the potential for growth, change, and knowledge development is enhanced” (Hartrick Doane & Varcoe, 2005, p. 9).

Religion and Spirituality

Religious and spiritual beliefs have major influences on the person’s attitudes toward health and illness, pain and suffering, and life and death. The distinction between religion and spirituality is often blurred. It is advisable for you to understand the various perspectives of patients. Many cultures do not separate religion and spirituality, whereas many others have totally distinct concepts of the two. To an Anglo-Canadian, for example, spirituality may mean an inner, personal relationship with a higher being. Although a discussion of religious and spiritual philosophies is difficult in a hospital setting, you need to assess what is important to the spiritual well-being of patients and learn as much as possible about their spiritual and religious practices (see Chapter 27).

Caring Beliefs and Practices

Caring beliefs and practices incorporate a patient’s perception of his or her ability to control circumstances or factors in the environment. Specifically, it may refer to a patient’s perception of how he or she can influence causes of illness and use cultural healing modalities and healers. During cultural assessment, you should identify the health practices of the patient and respect them (Box 9-6). Obtain information about folk remedies used and cultural healers employed by the patient. Unless these practices are harmful, they should be incorporated into the patient’s plan of care.

BOX 9-6 NURSING STORY

Identifying the Patient’s Health Care Practices

A Chinese immigrant who recently arrived in Canada has given birth to her first child. Once the newborn has been cared for and is resting, you ask the new mother if she would like to take a shower. The mother refuses politely. Her belief is that if she takes a shower, she could contract rheumatism in old age. Then the mother’s food tray arrives, and she does not touch or eat anything. For this newcomer to Canada, the hospital food may seem different and served in an unfamiliar manner. Her family brings plain rice and salted pork into the hospital. They also bring two different soups, which are thought to bring heat, the “yang,” into her body, thereby removing the impurities from her system.

In traditional Chinese culture, good health means achieving a balance between yin and yang. The belief is that all body systems interact with each other and with the environment to produce a balanced state of wellness. In consultation with the mother, you are able to assess and understand why she is refusing to shower and eat the hospital food. With this increased understanding, you are able to mutually negotiate with the mother some alternatives for her care to accommodate her needs, without jeopardizing her care or causing her distress. You appropriately assess that rather than showering, the mother would prefer a basin of water and a cloth that she could use to clean herself. With regard to her dietary requests, you determined that she can eat the food from home as long as it does not interfere with or jeopardize her health status. As a result, your sensitivity and respect for the new mother’s cultural beliefs enable her to relax and recover in a culturally safe environment. You were open to learning about the cultural beliefs of the new mother and then collaborating with her on decisions about care.

Experience With Professional Health Care

All cultures have concepts of past, present, and future dimensions of time. An aspect of a patient's experience with professional health care, for instance, may be your understanding of the patient's orientation of time. This information can be useful in planning care, arranging appointments for procedures, and helping a patient plan self-care activities at home. Differences exist in the concepts of time that cultures emphasize and in how time is expressed. Communication concerning time may be indirect and circular in order to avoid offending and disrespecting other people.

Present time orientation, for instance, may conflict with the policies of a health care institution that emphasizes punctuality and adherence to appointments. Improving patients' access to health services may be achieved by mutually negotiating schedules and by accommodating cultural patterns.

Application of Cultural Assessment Components to Aboriginal Peoples of Canada

Aboriginal peoples represent an important and growing group within Canada. In 2006, the number of people who identified themselves as Aboriginal (i.e., North American Indian [First Nations], Métis, and Inuit) surpassed 1 million (Statistics Canada, 2008a). Since the mid-1990s, the Aboriginal population has increased significantly. Between 1996 and 2006, it grew by 45%, nearly six times faster than the 8% rate of increase for the non-Aboriginal population (Statistics Canada, 2008a). In 2006, Aboriginal peoples accounted for almost 4% of the total population of Canada (Statistics Canada, 2008a). Of the three Aboriginal groups in Canada, the Métis population increased the most. Aboriginal peoples in Canada also increasingly live in urban centres. In 2006, 54% lived in urban areas (including large cities or census metropolitan areas and smaller urban centres); this proportion increased from 50% in 1996 (Statistics Canada, 2008a). Furthermore, the Aboriginal population is, on average, younger than the non-Aboriginal population. Almost half (48%) of the Aboriginal population consists of children and youth aged 24 and younger, in comparison with 31% of the non-Aboriginal population (Statistics Canada, 2008a).

The three Aboriginal groups—First Nations, Métis, and Inuit—have their own unique languages, heritages, cultural practices, and spiritual beliefs (Indian and Northern Affairs Canada, 2010). These groups contain many subgroups, each with its own unique culture. The term *Indian* describes all the Aboriginal peoples in Canada who are not Métis or Inuit. These include the nations or groups of people who were originally living in Canada before the European explorers began to arrive in the 1600s. Three legal definitions are used to describe Indians in Canada: Status, Non-Status, and Treaty Indians. Status Indians are registered under the *Indian Act* (Indian and Northern Affairs Canada, 2011), which regulates the management of reserves and sets out certain federal obligations. Non-Status Indians are not registered under the *Indian Act* (Indian and Northern Affairs Canada, 2011). A *Treaty Indian* is a Status Indian who belongs to a First Nation that signed a treaty with the Crown (Indian and Northern Affairs Canada, 2011).

Many Aboriginal people find the term *Indian* offensive and outdated; in the 1970s, the term *First Nation* became preferred to *Treaty Indians*. In addition, many Indian people adopted the term *First Nation* to replace the word *band* and also appended

the term *First Nation* to the name of their community, such as the *Nuxalk First Nation* (Indian and Northern Affairs Canada, 2011; Wasekeesikaw, 2010). Some Aboriginal people prefer the more inclusive term *First Peoples* rather than the word *Nation* because in English, *Nation* does not fit with the Aboriginal social structure. The first European explorers to arrive in North America used the term *Indian* because they thought they had reached India (Wasekeesikaw, 2010). First Nations peoples claim that the roots of the term *Indian* reflect a history of colonialism and that the term is, therefore, inappropriate (Wasekeesikaw, 2010).

What we refer to as “colonialism” is actually a theoretical framework for understanding the complexities of the relationship that evolved between Aboriginal peoples and Europeans as they came into contact and later sustained those initial relationships in building a new reality for both peoples in North America. Specifically, colonialism is the development of institutions and policies by European imperial and Euroamerican settler governments toward Aboriginal peoples (Alfred, 2009, p. 45).

The following sections describe variations from non-Aboriginal culture that exist among Canadian Aboriginal peoples. Bear in mind that these discussions are general in nature, and each patient needs to be assessed individually, as evidence demonstrates that many Aboriginal people and communities are healthy despite a history of colonization. Gerald Alfred's statement reflects the importance of being aware of this history and embracing a healing journey:

Yet informed opinion on the matter is clear, as the most recent compendium of top-level medical and social science research on mental health issues in Indigenous populations confirms that it is not indigenous dysfunction that is the root problem, but the dispossession of Indigenous people from the land and their subsequent oppressive treatment on reserves in the Indian Act system and in residential schools, and through other government policies. (Alfred, 2009, p. 47)

Ethnohistory

An understanding of specific cultural Aboriginal groups in Canada is important in order to appreciate contemporary health issues affecting Aboriginal peoples. The First Nations of Canada are exceptionally diverse, culturally, linguistically, socially, economically, historically, and in other ways. As Waldram et al. (2006) emphasized, “The recognition and acceptance of such diversity is essential to an appreciation of developments in the health care field and to an appreciation of the myriad processes that have affected the health status of Aboriginal people in both the pre-contact and post-contact periods” (p. 23).

Pre-European contact refers to the history of Aboriginal people before exploration and settlement of the Americas by Europeans. During that period, Aboriginal people were composed of distinct cultures from the Arctic, Western Subarctic, Eastern Subarctic, Northeastern Woodlands, Plains, Plateau, and Northwest Coast. Traditional health beliefs, shamans, herbalists, and folk medicine were aspects of how Aboriginal communities experienced healing and well-being. **European contact** began on Canada's east coast, where French explorers and fur traders settled and introduced diseases such as smallpox, tuberculosis, and measles, which killed thousands of Aboriginal people. Scarce resources diminished Aboriginal livelihoods, and malnutrition, starvation, and alcohol consumption made circumstances worse (Dickason, 2006). During

post-European contact, Europeans established relationships with Aboriginal people, and colonization influenced Aboriginal systems of government, trade, and health care. Over the years, the Canadian government displaced Aboriginal people from their traditional lands and developed policies to isolate them and assimilate them into Canadian society, which resulted in the destruction of Aboriginal cultures. These oppressive and suppressive policies, and the acts that followed, had extensive negative effects on Aboriginal cultural identities and governance (Wasekeesikaw, 2010). The Indian residential school system, for instance, which no longer exists in Canada, left a multi-generational legacy of physical and psychological abuse that “lives on in the form of significant pain and suffering among residential school survivors and their families” (Barton et al., 2005b, p. 295).

Social Organization

Many First Nations peoples live on reserves and in communities in each of the Canadian provinces and territories, and many Inuit live in settlements throughout the territories. The reserves are easily accessible in the southern regions but remote and isolated in the northern regions. Métis live in communities across Canada and in settlements set aside for them in Alberta. For many Aboriginal people, the biological family is the traditional centre of social organization and includes all members of the extended family. The principles that guide family and community social organization by which they live their lives include the notion of wholeness, whereby “all things are interrelated, and everything in the universe is part of a signal whole. Everything is connected in some way to everything else, and it is only possible to understand something if one understands how it is connected to everything else” (Hunter et al., 2004, p. 274).

Socioeconomic Status

Cultural disorganization resulting from colonization underpins the culture of poverty, circumstances that are experienced by many Aboriginal people in contemporary Canadian society. Large proportions of the Aboriginal population live in remote communities (Statistics Canada, 2008a) and travel back and forth between rural and urban environments. In general, the Aboriginal population experiences both poorer health and reduced access to health services in comparison with most Canadians living in rural and urban locations. Along with other inequities and social injustices that contribute to their vulnerability, they are socially, economically, and politically marginalized from mainstream society. “Thus, there is a complex interplay between geographical context and the historical socio-economic and political context of Aboriginal people’s health, and it has profoundly influenced the health and social status of Aboriginal Canadians” (Tarlier et al., 2007, p. 129).

Biocultural Ecology and Health Risks

Since the 1950s, dramatic changes in lifestyle have affected the social, environmental, and health status of Aboriginal people (Waldram et al., 2006). The disease patterns in many First Nations and Inuit communities continue to resemble those found in low-income countries, despite improvements since the 1990s (Health Canada, 2011b). First Nations people and Inuit experience serious health-related challenges related to high rates of chronic and contagious diseases and shorter life expectancy (Health Canada, 2011b). In addition, the prevalence of major chronic diseases, including diabetes, cardiovascular

disease (1.5. times higher), cancer, arthritis, and rheumatism, appears to be increasing in this population (Gracey & King, 2009; Health Canada, 2011b; King et al., 2009; Vollman et al., 2012). Rates of unintentional injuries, deaths from drowning, and other accidents are also high among children and families in Aboriginal communities (Vollman et al., 2012).

Tuberculosis. Although the overall incidence of tuberculosis has dropped steadily since the 1960s, the incidence among First Nations and Inuit people is eight to ten times higher than the national rate (Health Canada, 2011b). Factors contributing to such a high rate include overcrowding and unsafe or unreliable water supplies in these communities.

Diabetes Mellitus. Viewed as an epidemic in progress for Canadian Aboriginal peoples, diabetes has a prevalence (dependent on location) that is three to five times higher in this population compared to non-Aboriginal Canadians (Health Canada, 2011a). Contributing factors associated with this rate are based on research that involves an integrated understanding of genetic susceptibility, changes associated with transitioning from a physically active lifestyle to a sedentary lifestyle, and the consumption of a high sugar, fats, and salt diet. Type 2 diabetes is diagnosed with increasing frequency in Aboriginal children (Health Canada, 2011a). Earlier onset of the disease leads to an earlier onset of complications, as well as excessive mortality rates among young and middle-aged adults. In Inuit communities, the rate of diabetes is still relatively low, but concerns have been raised that this may change if the Inuit alter their traditional eating patterns and lifestyle (Health Canada, 2011a). In July, 2010, the Government of Canada announced through a news release that it would continue to support the Aboriginal Diabetes Initiative (ADI), in order to address the high rates of diabetes among Aboriginal peoples living on-reserve, as well as off-reserve. Background information from Health Canada states:

“Established in 1999, the Aboriginal Diabetes Initiative (ADI) had initial funding of \$58 million over five years. It was then expanded in 2005 with a budget of \$190 million over five years. Budget 2010 included a commitment of \$110 million over two years for the ADI. The ADI’s main objective is to reduce type 2 diabetes by supporting health promotion and disease prevention activities and services, delivered by trained community diabetes workers and health service providers. Renewed funding will enable First Nations and Inuit communities to continue to build on past successes in more than 600 communities throughout Canada. The ADI delivers a range of primary prevention, screening and treatment programs in partnership with Tribal Councils, First Nations organizations, Inuit community groups and Provincial and Territorial governments. Through these activities, the ADI supports prevention, health promotion, screening and care management initiatives that are community-based and culturally appropriate. The renewed ADI will feature several areas of enhanced focus, including:

- Initiatives for children, youth, parents and families;
- Diabetes in pre-pregnancy and pregnancy;
- Community-led food security plans to improve access to healthy foods, including traditional foods; and,
- Enhanced training for home and community care nurses on clinical practice guidelines and chronic disease management strategies.

Using local knowledge, First Nations and Inuit communities are encouraged to develop innovative, culturally relevant approaches aimed at increasing community wellness and ultimately reducing the burden of type 2 diabetes. Community

activities funded through the ADI vary from one community to another, and may include walking clubs, weight-loss groups, diabetes workshops, fitness classes, community kitchens, community gardens and healthy school food policies. The ADI also supports traditional activities such as traditional food harvesting and preparation, canoeing, drumming, dancing and traditional games. The ADI supports a network of over 300 trained community diabetes prevention workers via active training programs and the sharing of best practice models and approaches" (http://www.hc-sc.gc.ca/ahc-asc/media/nr-cp/_2010/2010_129bk-eng.php).

HIV and AIDS. Human immunodeficiency virus (HIV) infections and cases of acquired immune deficiency syndrome (AIDS) among Canadian Aboriginals have increased steadily since the 1990s, whereas the annual number of AIDS cases has levelled off in the rest of the population. Aboriginal peoples are overrepresented among HIV and AIDS cases in Canada; although Aboriginal persons make up about 3.8% of the Canadian population, it is estimated that they represent about 8.0 % of all those living with HIV and AIDS (Public Health Agency of Canada [PHAC], 2010). In addition, the HIV infection rate is about 3.6 times higher among Aboriginal persons than non-Aboriginal persons. Between 1996 and 2006, Aboriginal persons with HIV and AIDS differed significantly from non-Aboriginal persons. Compared to their non-Aboriginal counterparts, Aboriginal persons who are diagnosed with HIV were more likely to be younger (32.4 % versus 21% under age 30), female (48.1% versus 20.7%), and infected through intravenous drug use (53% versus 14%) (PHAC, 2010).

Alcohol and Substance Abuse. It is difficult to collect accurate data, but the abuse of alcohol and other substances is perceived to be common in some Aboriginal communities (Health Canada, 2011d). Alcohol and substance abuse can be viewed as part of a set of complex issues affecting the social and physical well-being of the patient, the family, and the community. The National Native Alcohol and Drug Abuse Program was established to assist First Nations and Inuit community members in instituting and operating programs aimed at reducing the level of alcohol, drug, and solvent abuse among target groups on reserves. The program emphasizes prevention and treatment, as well as training, research, and development.

Suicide. The suicide rates in Inuit and First Nations communities are five to six times higher than the rates found in the non-Aboriginal population (Health Canada, 2012b). Although there is much variation among communities, suicide rates are five to seven times higher for First Nations youth than for non-Aboriginal youth; suicide rates among Inuit youth are eleven times the national average, among the highest in the world (Health Canada, 2012b). Possible factors contributing to the suicide rate include psychobiological factors (pre-existing mental illness, personality disorders, dysfunctional cognitive style), situational life history factors (early childhood trauma, family dysfunction, substance abuse, conflict with authority, absence of spirituality), socioeconomic factors (poverty, unemployment), and cultural stress (low self-esteem, lack of cultural heritage) (Waldram et al., 2006).

Aboriginal Women and Violence. According to the 2009 General Social Survey (GSS), approximately 67,000 Aboriginal women aged 15 or older across the provinces self-reported they had experienced one or more crimes of a violent nature, such as sexual assault, robbery, and physical assault, in the 12 months prior to the survey. This rate is almost three times higher than the rate reported by non-Aboriginal women

Intergenerational Trauma: Convergence of Multiple Processes Among First Nations Peoples in Canada

Traumatic events exact an enormous psychological and physical toll on survivors and often have ramifications that must be endured for decades. This includes emotional scars, and in many cases standards of living are diminished, often never recovering to levels that existed prior to the trauma. These traumas can occur at a personal level (e.g., car accident, rape) or at a collective level (war, natural disaster, genocide), and the responses to such events are not identical. In the latter instance, there is now considerable evidence that the effects of trauma experiences are often transmitted across generations, affecting the children and grandchildren of those who were initially victimized. The present review is meant to describe the immediate and intergenerational impacts of traumatic events in First Nations people. In this regard, particular attention is devoted to how intergenerational effects may come about, with particular focus on the influence of socioeconomic disadvantages (e.g., living conditions) and parental styles that might be secondary to traumatic events. Importantly, however, collective trauma may have profound intergenerational effects that infiltrate beyond easily observed or measured factors that come from the survivors telling and retelling of trauma (or in contrast, by the deep silence that is common among some survivors) (Bombay et al., 2009, p. 6).

Intergenerational trauma: convergence of multiple processes among First Nations peoples in Canada. *Journal of Aboriginal Health*, November, 6–47.

and represents about two-thirds (63%) of Aboriginal females aged 15 to 34. The survey also revealed that three-quarters (76%) of violent incidents involving Aboriginal women that were committed by someone other than a spouse or common-law partner were not reported to the police, compared with 70% for non-Aboriginal women (Health Canada, 2009) (Box 9-7).

Language and Communication

Approximately 53 Aboriginal languages exist, with Algonquian being the largest and most widespread language family in Canada (Dickason, 2006). Many of these languages have identifiable dialects. Interpreters who can speak the various dialects within a language are invaluable, but locating them poses challenges to the health care system. Knowledgeable interpreters, however, not only understand and translate the patients' words but also interpret the culture and make relevant the concepts underlying it as well. For some Aboriginal Canadians, for instance, it is important to realize that reflection may lead to gaps, and thus long silences, in the conversation (Watts & McDonald, 2007).

Religious and Spiritual Practices

The spiritual approaches of Aboriginal peoples incorporate a mind-body-spirit connection that is harmonious with nature. For some, the circle of life is often viewed as having four aspects or directions: spiritual, physical, mental, and emotional. The presence of all components together enables the person to heal the self and restore well-being. It is in the understanding of wholeness that the spiritual, physical, mental,

emotional, and relational parts of the self are integrated. Transcending these dimensions, however, is the spiritual component, which assists the person in discovering his or her human potential (Hunter et al., 2004).

Caring Beliefs and Practices

Aboriginal peoples subscribe to a holistic concept of health but exemplify tremendous diversity of background and experience with regard to culture, language, and traditions (Wasekeesikaw, 2010). The caring beliefs and practices of various groups are linked to being alive and well, which may be understood as the interconnected relationship people create with the land and the plants and animals of nature. Aboriginal health and healing incorporates many aspects within the circle of life that includes, for instance, being human, stewarding the land, hunting wild animals, eating traditional foods, and practising herbal medicine. In a study that focused on the experience of diabetes among Aboriginal people living in a rural Canadian community (Barton et al., 2005a), the findings revealed cultural themes associated with Western and traditional medicines; dietary changes, exercise, and weight loss; culturally relevant communication; Aboriginal life choices and the responsibility to choose; and a belief in living day by day. Within this particular First Nations community, the researchers found that “(i) consultative meetings with community members; (ii) the use of a cultural awareness program for health professionals; and (iii) the involvement of Aboriginal people in the development of their own diet, exercise and prevention strategies would greatly enhance [diabetes] programs in the future. [Such initiatives] could contribute not only to the culturally safe management of diabetes, but also encourage its early detection now and in the future” (Barton et al., 2005a, p. 245).

Experience With Professional Health Care

Although cultural sensitivity frameworks will guide you in your relationships with patients, systematized and taxonomic descriptions of characteristics particular to a cultural group do not always “accommodate peoples’ diet preferences, communication styles, family dynamics, and culturally-based responses to pain, child-birth, childrearing, etc.” (Browne & Varcoe, 2006, p. 158). You need to ask yourself how you can think about notions of culture without stereotyping or thinking simplistically about Aboriginal people and without inciting hurtful and nonconstructive assumptions about cultural difference (Box 9-8). In contemplating this question, Dion Stout and Downey (2006) described the conceptual links between nursing, Aboriginal peoples, and cultural safety. They contended that (1) “the caring spaces that are occupied by Indigenous people and nurses are also potentially the new arenas of struggle for both sides”; (2) “attention between the totality of self and the totality of one’s environment is inherent in cultural safety affecting both nurses and Indigenous people”; and (3) “an overemphasis on culture as a health determinant can bring about an abdication of responsibility over all other health determinants by health determiners like Indigenous people and nurses” (p. 327) (Box 9-9).

Implications for Nursing Practice

The importance of cultural competency and safety for health care administrators, practitioners, and educators has been recognized by the National Aboriginal Health Organization (NAHO). NAHO’s (2008) document describes the origins of

BOX 9-8 RESEARCH HIGHLIGHT

Contemporary Perceptions of Health From an Indigenous (Plains Cree) Perspective

“Currently, there is limited literature demonstrating awareness of how contemporary Aboriginal peoples understand and define health, address their health concerns, and perceive barriers to obtaining optimal health. This knowledge is an important and essential first step in program planning for delivering effective health care for all aspects of health. An additional challenge is to effectively address and meet these needs in a timely manner which is critical to overall Indigenous wellness. The primary researcher, who is Indigenous (Plains Cree), wondered whether the social determinants of health were reflective and an appropriate framework to address the existing health disparities between Aboriginal and non-Aboriginal Peoples of Canada, and more specifically, the Plains Cree people from Thunderchild First Nation. [Their] paper examines the results from a qualitative descriptive research study completed in Thunderchild First Nation, Saskatchewan. There were four predominant themes that were derived from the data: health was consistently described in relation to physical, mental (intellectual), emotional, and spiritual wellness; value of health; factors related to the environment; and factors related to economics. Collectively, there does appear to be a holistic perception of health, similar to the teachings from the Medicine Wheel. Pursuing and maintaining health included a combination of information and practices from both the western and Traditional Indigenous world. This data supports that the determinants of health may be an appropriate framework to address the health needs of Indigenous Peoples, and an appropriate frame for federal, provincial and local policy makers to implement structural changes necessary to decrease the health disparities between the Indigenous Peoples and the rest of Canada” (Graham & Stamler, 2010, p. 6).

BOX 9-9 CASE STUDY

Mentorship Project: An Aboriginal Man With HIV

James is a 50-year-old two-spirited man from the Muskoday First Nation in northern Saskatchewan. He recently saw his family doctor in Prince Albert for an HIV test. When he returned to see the doctor for his results, he was very shocked to learn that his test was positive. James had lived with his partner, Sam, for more than 10 years; however, they separated about seven months ago. James is unsure of Sam’s HIV status.

As one of the nurses working in the STI clinic, James has been referred to you for an assessment. During his first visit to see you, James was very quiet and withdrawn, and it was difficult to engage him in a conversation. James would like return to his home community to live but is very hesitant to do this because he is afraid that he will not be accepted. He receives his medical care based on his First Nations status; however, he is worried that care for his HIV illness will not be covered.

1. How do you think you could demonstrate compassionate, culturally safe relationship-centred care with this patient?
2. How could you demonstrate effective and culturally safe communication with this patient?

cultural competency and cultural safety; a theoretical and methodological approach to cultural safety, an approach that originated with Aboriginal peoples; and the importance of its application to health care.

Increasingly, nurse scholars are researching the health challenges faced by Aboriginal peoples and providing an analysis of health policy (Smye & Brown, 2002). The exploration of cultural safety is also being taken up by other disciplines. From a sociological perspective, Brascoupé and Waters in a research paper define “cultural safety and how it differs from cultural competence or trans-cultural training and practices; shows why it’s important to move from the concept of cultural safety to the outcome of cultural safety, namely the success of an interaction; explores the idea of a shift from cultural safety for individuals to cultural safety at institutional and policy levels; and provides recommendations in five areas” (Brascoupé & Waters, 2009, p. 6). With regard to the success of an interaction, Harrowing et al. (2010) emphasize such an outcome begins with awareness of “the nurse’s reflection on his or her personal and cultural history, values, and beliefs and continues with the situating of those understandings within a framework of power imbalances, institutional discrimination, and colonizer-colonized relationships (p. 246). This is illustrated in the work of Smith et al. (2006) focused on establishing safety and responsiveness as a mainstay of care for pregnant and parenting Aboriginal people. Their findings revealed “that safety and healthcare relationships and settings, and responsiveness to individuals’ and families’ experiences and capacities must be brought into the forefront of care. [These] results suggest that the intention of care must be situated in a broader view of colonizing relations to improve early access to, and relevance of, care during pregnancy and parenting for Aboriginal people” (p. E27).

Reutter and Kushner (2010) in their article argue “that nursing has a clear mandate to ensure access to health and health-care by providing sensitive empowering care to those experiencing inequities and working to change underlying social conditions that result in and perpetuate health inequities” (Reutter & Kushner, 2010, p. 269). One reason why people become nurses is a desire to “act in ways that are respectful, compassionate, and equitable and that leave [nurses] feeling that [they] have somehow ‘done good’” (Hartrick Doane & Varcoe, 2005, p. 16). A relational approach to nursing shapes the places of inquiry and practice that determine how to find your way through relationships, culture, safety, ethics, diversity, power, economics, communication, and history. A deep consideration of **relational practice** and nursing obligations offers you the means to understand experience and to imagine how you might incorporate reflexivity, intentionality, and openness into practice, education, and research. It is from such a position of nursing inquiry that we are better able to interpret our own personal life threads and to elicit from enmeshed personal and professional life stories the insight and wisdom that guide us to becoming better human beings.

In regard to practice, Hartrick Doane and Varcoe (2007) present an example of a nurse recalling the interaction with an elderly woman in the emergency department who needed to be invited to reveal her “whole” experience. The woman’s story “exemplifies the significance of a nurse-patient relationship and the profound difference it can make in promoting health and healing” (p. 195). In the area of education, Smith and colleagues (2007) describe “community based stakeholders’ views of how safe and responsive care ‘makes a difference’

to health and well-being for pregnant and parenting Aboriginal people.” They concluded that “design and evaluation of care based upon community values and priorities and using a strengths-based approach can improve early access to a relevance of care during pregnancy and parenting for Aboriginal people” (p. 321). In considering research, Barton (2004) focuses on a form of narrative inquiry as a relational method of critically analyzing its appropriateness as an innovative approach to researching Aboriginal people’s experience of living with diabetes. By locating Aboriginal knowledge in a relational method such as narrative inquiry, “the ability to adapt a methodology for use in a cultural context, preserve the perspectives of Aboriginal peoples, maintain the holistic nature of social problems, and value co-participation in respectful ways are strengths of an inquiry partial to a responsive and embodied scholarship” (p. 519).

✦ KEY CONCEPTS

- Global health is an encompassing term with an understanding of the scope of the problems and not their location.
- Global citizenship is the active engagement of nurses becoming global citizens in identifying and acting on health inequities in the population they work with at the local, national, and international levels.
- Culture is the context for interpreting human experiences such as health and illness and provides direction for decisions and actions.
- Transcultural nursing is a comparative study and understanding of cultures to identify culture-specific and culture-universal caring constructs across ethnic groups.
- Culturally congruent care is meaningful, supportive, and facilitative because it conforms to valued life patterns of patients; it is achieved through cultural assessment.
- Culturally competent care requires knowledge, attitudes, and skills supportive of implementation of culturally congruent care.
- Cultural safety is an outcome of nursing education that enables safe service to be defined by patients who receive the service.
- Cultural assessment requires a comprehensive inquiry into the patient’s cultural values, beliefs, and practices; it may involve assessing ethnohistory, social organization, socioeconomic status, biocultural ecology and health risks, language and communication, religion and spirituality, caring beliefs and practices, and experiences with professional health care.
- Relational practice is the nursing obligation to examine relationships, ethics, and effective nursing practice, and the personal and contextual elements that continuously shape and influence nursing relationships.

✦ CRITICAL THINKING EXERCISES

1. You are about to begin giving an Arab Muslim man his morning care when he states, “I don’t want a bath now.” He becomes annoyed when you try to explain that you must give him a bath at this time. Before you leave the room, he asks you to leave a basin of water and towel by his bedside. He also asks you to get his prayer rug from his closet.
 - a. How should you respond to the patient?
 - b. What may be the reasons for his refusal and annoyance?
2. A 50-year-old Chinese woman is hospitalized with a respiratory condition. She insists that you give her warm water and rub her back with Tiger Balm liniment. When she receives her lunch, consisting of a turkey sandwich, tossed salad, and milk,

she keeps the turkey sandwich and tossed salad but asks that you take the milk away.

- a. How should you respond to the patient's requests?
 - b. What is the significance of her requests?
 - c. Why does she refuse her lunch?
3. You are assigned to a 60-year-old South Asian Hindu widow who is admitted with chest pain and shortness of breath. The patient recently arrived from India to visit her son and pregnant daughter-in-law. She can speak only Gujarati and understands very little English. She is accompanied by her son.
- a. What areas should you include in your focused cultural assessment?
 - b. How should you communicate with the patient?
 - c. Identify ways to preserve and accommodate the patient's culture in her care.
 - d. What aspects of the patient's way of life may need to be modified?

✦ REVIEW QUESTIONS

1. Socialization into one's primary culture during childhood is known as
 1. Enculturation
 2. Acculturation
 3. Assimilation
 4. Multiculturalism
2. Multiculturalism results when a person
 1. Has an experience with a new or different culture that is extremely negative
 2. Maintains his or her culture and interacts peacefully with people of other cultures
 3. Gives up his or her ethnic identity in favour of the dominant culture
 4. Adapts to and adopts a new culture
3. Cultural awareness involves an in-depth self-examination of one's
 1. Background, recognizing biases and prejudices
 2. Social, cultural, and biophysical factors
 3. Engagement in culturally safe interactions
 4. Motivation and commitment to caring
4. Culturally safe care is the process of
 1. Learning about vast cultures
 2. Delivering care that is based on knowledge of the patient's cultural heritage, beliefs, and attitudes
 3. Influencing treatment and care of patients
 4. Motivation and commitment to caring
5. Ethnocentrism is the root of
 1. Stereotypes, biases, and prejudices
 2. Meanings by which people make sense of their experiences
 3. Cultural beliefs
 4. Individualism and self-reliance in achieving and maintaining health
6. When a person acts on his or her prejudices,
 1. Discrimination occurs
 2. Sufficient comparative knowledge of diverse groups is obtained
 3. Delivery of culturally congruent care is ensured
 4. Effective intercultural and relational communication develops
7. The prevailing value orientation in Western society is
 1. Use of rituals symbolizing the supernatural
 2. Group reliance and interdependence
 3. Healing emphasizing naturalistic modalities
 4. Individualism and self-reliance in achieving and maintaining health
8. Disparities in health outcomes between rich and poor patients illustrate
 1. The attribution of illness to natural, impersonal, and biological forces
 2. Biological and sociocultural health risks
 3. Influence of socioeconomic factors in morbidity and mortality
 4. Combination of naturalistic, religious, and supernatural modalities
9. Global health is a concept that focuses
 1. On issues that affect the health of the population of a particular community or country
 2. Mainly on prevention programs for populations
 3. On issues that directly or indirectly affect health but that can transcend national boundaries
 4. On a few disciplines, but has not emphasized multidisciplinary
10. The prevailing values in Western society on individual autonomy and self-determination
 1. Rarely have an effect on other groups
 2. Do not have an effect on health care
 3. May hinder ability to get into hospice programs
 4. May be in direct conflict with the values of diverse groups

Nursing Leadership, Management, and Collaborative Practice

Written by Susan M. Duncan, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Describe entry-level professional nurse competencies related to leadership, management, and collaborative practice.
- Describe the relationships between nursing leadership and healthy practice environments, patient safety, and quality patient care outcomes.
- Discuss how a nurse leader can contribute to collaborative practice and best practices implementation.
- Discuss ways to apply skills of clinical care coordination in nursing practice.
- Discuss principles for the appropriate delegation of patient care activities.
- Describe the purpose, elements, and models for quality practice environments and patient safety.
- Identify strategies for developing entry-level competencies related to management and leadership in nursing.

key terms

Accountability, p. 132	Interprofessional teams, p. 129
Authority, p. 132	Intraprofessional teams, p. 129
Autonomy, p. 132	Leadership and management, p. 125

All nurses must be leaders, and nurses assume positions of leadership and management in health care delivery much earlier in their careers today than in previous generations: "Nursing leadership is about nurses who understand that the development of nursing leaders must begin at the outset of every nursing education program and continue throughout the career of every nurse" (Canadian Nurses Association [CNA], 2009b). It is therefore important that you develop an understanding of **leadership and management** roles in nursing early in your educational program and the relevant competencies required of entry-level nurses. As you develop the knowledge and skills to enter the nursing workforce, you also learn how to become a leader among colleagues for the delivery of care in many health care settings. Phrases such as "from the bedside to the boardroom" (Institute of Medicine [IOM], 2011) and "nurse educators must prepare students to lead where they land" (Fugate Woods, 2003, cited in CNA, 2009b) indicate the centrality of leadership in all nursing practice settings and roles. You can see from the list of competencies required of entry-level nurses in Box 10-1 that leadership begins

► BOX 10-1

Entry-Level Staff Nurse Competencies Related to Leadership and Management

- Is accountable and responsible for own actions and decisions, including personal safety
- Demonstrates leadership in providing patient care by promoting healthy and culturally safe work environments
- Displays initiative, self-confidence, and self-awareness, and encourages collaborative interactions within the nursing and health care team
- Organizes own workload and develops time-management skills for meeting responsibilities
- Integrates quality improvement principles and activities into nursing practice
- Uses relational knowledge and ethical principles when working with students and other health care team members to maximize collaborative patient care
- Participates in and contributes to nursing and health care team development
- Supports professional efforts in the field of nursing to achieve a healthier society (e.g., lobbying, conducting health fairs, and promoting principles of the *Canada Health Act*)
- Demonstrates an awareness of healthy public policy and social justice
- Develops support networks with registered nurse (RN) colleagues, health care team members, and community supports

Adapted from College of Registered Nurses of British Columbia. (2009). *Competencies in the context of entry-level registered nurse practice in British Columbia. Leadership and management practices for healthy work environments*. Vancouver: Author. Retrieved from <https://www.crnbc.ca/Registration/Lists/RegistrationResources/375CompetenciesEntryLevelRN.pdf>.

with a strong professional identity and accountability. For optimal nursing care, managers and leaders are needed to ensure both the vision for quality care and the management skills required for best practices and quality care (Hibberd et al., 2006). Whereas *leadership* refers to a shared vision, values, organizational strategy, and relationships, *management* most often refers to the competencies required to ensure the day-to-day delivery of nursing care according to available resources and standards of professional practice. To be effective in promoting a healthy work environment and a healthy society, nurses must demonstrate leadership practices that honour the importance of relationships, values, and transformational change in health systems (Cummings, 2004; Gifford et al., 2006; IOM, 2011; Pearson et al., 2007). Nursing leadership is needed at every level, and nurses must be full partners in change with physicians and other professionals and sectors of society (IOM, 2011). Figure 10-1 provides a conceptual model of **transformational leadership** practices that have been identified as contributing to health **outcomes**. Researchers identify that transformational and relational models of leadership best contribute to healthy work environments for nurses, including nurse retention and recruitment (Cummings et al., 2010).

In the current context of health care in which qualified care providers are in short supply, competencies associated with leadership in nursing relate to creating environments for healthy working relationships and teamwork. A healthy work environment is most likely to retain nurses in practice settings in which they are both satisfied and able to provide high-quality care. RNs must work collaboratively with other

members of the nursing team, as well as with professionals from other disciplines and with patients and families.

The importance of such work is most often discussed as **collaborative practice**, defined as working together toward mutually identified goals while valuing different perspectives and accountabilities of individual team members (Gardner, 2005; Registered Nurses' Association of Ontario [RNAO], 2010b). This chapter therefore focuses on current thinking in nursing leadership and management, including definitions, roles and relationships, shifts to collaborative practice models, and the role of leaders in ensuring healthy practice environments and best practices. The ideas and examples included in this chapter apply to the different practice settings in which nurses work: in homes, in institutions, and in communities.

Management and Leadership Roles for Nurses

Nurses assume a wide variety of management and leadership roles in health care organizations in order to ensure that patients receive safe and high-quality care. Research has revealed that nurses must provide leadership to ensure that nursing care takes place in quality practice environments (Aiken et al., 2002, 2008; Health Canada, 2002; Pearson et al., 2007) and that these work environments are essential for health, high-quality patient care, and patient safety (Estabrooks et al., 2005; Wong & Cummings, 2007). A high-quality practice environment is also a healthy work environment, defined as “a practice setting that maximizes the health and well-being of nurses, quality patient outcomes, organizational performance and societal outcomes” (RNAO, 2010a, p. 13).

A **healthy practice environment** begins with the senior nurse leader in the organization, who most often holds the title of Chief Nurse Executive, Chief Nursing Officer, or Director or Vice-President of Nursing or of Patient Care (Health Canada, 2002). In 1999, the government of Canada instituted the first Office of Nursing Policy with Dr. Judith Shamian, RN, Executive Director, hired to provide leadership to ensure that attention was paid in government to the nursing perspective on programs and policies (Health Canada, n.d.). Since then, several provinces have followed suit, instituting provincial nursing policy offices led by nurses in executive positions. These positions are key to ensuring that nurses influence the policy directions that governments take to ensure high-quality nursing services for Canadians. In policy roles, nurses act as policy advocates and as such have made a difference throughout history; they continue to advocate today for progressive public policy in primary health care and to achieve health equity (Reutter & Kushner, 2010) (see Unit I). As a student, you will learn the skills involved in nursing advocacy and assume the role of advocate to promote the health of people. Nurses today “stand on the shoulders of giants”; the nurse leaders of the past held a powerful vision for the development of nursing as a profession and advocated tirelessly to bring this vision to fruition (“A century of progress,” 2005). One such leader was Ethel Johns, director of the University of British Columbia's first nursing school. She inspired other nurses with her vision and challenged them to think for themselves (Boxes 10-2 and 10-3).

Nursing Care Delivery Models, Collaborative Practice, and Nursing Teams

As in the past, a strong nurse executive unites the strategic direction of the organization with the values and goals of

Figure 10-1 Conceptual model for developing and sustaining leadership. This model organizes and guides the discussion of the Registered Nurses' Association of Ontario (RNAO) recommendations. It provides a framework for understanding the leadership practices needed to achieve healthy work environments and the organizational supports and personal resources that enable effective leadership practices. **Source:** From Registered Nurses' Association of Ontario. (2010, March). *The healthy work environments quick reference guide for nurses* (p. 23). Toronto: Author.

BOX 10-2 Milestones in Canadian Nursing History

Ethel Johns, 1879–1968

A 1902 graduate of the Winnipeg General Hospital School of Nursing, Ethel Johns served as head nurse of several units at this hospital before becoming the first staff nurse to oversee its X-ray department. In 1907, she assumed editorship of its *Nurses Alumnae Journal* and began contributing to *Canadian Nurse*. Her literary talent, combined with her ability to challenge nurses to think independently, led to her nomination for membership in the Canadian Women's

Press Club in 1911. In 1913, Johns took a position as head surgical nurse at Good Samaritan Hospital in Los Angeles. After returning to Manitoba in 1915, she assumed the post of superintendent of the Children's Hospital of Winnipeg. She also worked tirelessly for the registration of nurses in Manitoba. Johns held strong convictions about social issues and nursing, and she supported needed reforms. During the Winnipeg General Strike of 1919, her pro-labour views led her into conflict with the Children's Hospital board of directors, and she resigned.

Subsequently, Johns was appointed director of the Department of Nursing at the University of British Columbia, which offered the first Canadian university degree program in nursing. In 1929, she became director of nursing studies at New York Hospital, Cornell Medical College. She also worked on a landmark study of nursing education in the United States. In 1933, Johns became editor of *Canadian Nurse*, which enabled her to communicate with a wide audience of nurses. Dr. Rae Chittick, president of the CNA during Johns's tenure as editor, praised Johns for bringing to the position "a world perspective on nursing, a hospitality of the mind from her rich experience . . . She . . . reached out to challenge nurses to think for themselves and to create a body of nursing opinion on the changes essential to meet the health needs of a rapidly expanding nation." In 1947, Johns helped establish a new journal, *Just Plain Nursing*, which continued publication for the next 13 years. Also in 1947, Johns Hopkins Hospital asked her to write a history of its School of Nursing; this history was published in 1953. Later, she published the *Winnipeg General Hospital School of Nursing, 1887–1953*.

The CNA awarded Johns the Mary Agnes Snively Memorial Medal in 1940 and an honorary life membership in 1958 in recognition of her leadership in Canadian nursing.

Based on Street, M. M. (1973). *Watch-fires on the mountains: The life and writing of Ethel Johns*. Toronto: University of Toronto Press.

BOX 10-3 FOCUS ON PRIMARY HEALTH CARE

Nursing Leadership in Primary Health Care

Nursing as a profession has taken a strong leadership role in implementing primary health care throughout the world. Since 1978, the International Council of Nurses, the CNA, and other national, provincial, and territorial nursing associations have been instrumental in lobbying for inclusion of primary health care principles and programs in health care professional education, in service planning and delivery, and in research and evaluation. The CNA (2009a) actively promotes initiatives to incorporate primary health care into nursing practice and policy. Primary health care principles enshrined in policy is the way to promote health for all people and is based on social justice model and values (Reutter & Ogilvie, 2011). Nursing advocacy for primary health care as the foundation of health care is required of leaders at all levels of practice and organizations (International Council of Nurses, 2008; Reutter & Kushner, 2010).

There is reason to believe that nurses must play an even larger role in primary health care in the future (Duncan & Whyte, 2010; World Health Organization [WHO], 2008) to provide leadership necessary for transformational change in health systems worldwide. WHO (2008) calls for a greater emphasis on primary health care to reform health

systems worldwide, a process of change that will require nurses everywhere to provide leadership by demonstrating commitment to the values and principles of PHC and envisioning new roles and opportunities to promote health.

If nurses are to have the influence that is needed to transform health systems, they must develop the vision, knowledge and skills for primary health care. Nurses learn to influence systems through their work in organizations and most importantly by working collectively in nursing and other types of associations. Nursing associations have a pivotal role to play in ensuring that the voice and influence is expressed and represented as the largest group of health professionals worldwide:

"The ICN and its member national nurses associations (NNAs) promote and support all efforts to improve the preparation of nurses for management, leadership and policy development. The preparation should be broad and must include the development of knowledge and skills for influencing change, engaging in the political process, social marketing, forming coalitions, working with the media and other means of exerting influence" (ICN, 2008).

nursing. Nurse executives must also build teams of leaders who work across the organization to implement best practices and develop high-quality work environments in which nursing practice can flourish. Although it takes a strong senior nursing leader to inspire a healthy work environment, the role and responsibility of every nurse is to provide leadership to make a difference by (CNA, 2009b) displaying attributes such as articulating a vision, enabling others to act, encouraging others, and taking initiative. The leader and nursing staff must share a philosophy of care that integrates purpose, best practices, and concern for relationships, including how staff will work together and with patients and families (Box 10-4).

Integral to the philosophy of care is the selection of a nursing care delivery model and a management structure that support professional nursing practice. Ideally, the vision for patient care should drive the selection of a care delivery model (RNAO, 2010a). A nursing care delivery model is a system for organizing and delivering nursing care to patients and their families, and it represents structural and contextual elements of nursing practice (Fowler, Hardy & Howarth, 2006, cited in CNA, Canadian Council for Practical Nurse Regulators & Registered Psychiatric Nurses of Canada [in press]). Key factors contributing to success are strong nursing leadership, decision-making authority for nurses who provide direct care, and effective respectful communications with colleagues, physicians, and other health care providers (Health Canada, 2002; Canadian Patient Safety Institute, 2009; Hinshaw, 2008; Manojlovich et al., 2008).

Nursing care delivery models are designs that determine how nurses provide care. Historically, the choices of a nursing care delivery model have been influenced by the social and economic conditions, and this is the case today when care models are changing because of a shortage of nurses and other health care providers (Manojlovich et al., 2008). **Continuity of care** is an extremely important concept in determining the choice of a nursing care delivery model. *Continuity of care* is defined as "a seamless continuous implementation of a plan

➤ BOX 10-4

Developing a Vision for a Nursing Unit or Program

What Is the Nursing Unit's Purpose or Mission?

- Articulating why it exists
- Ensuring that nursing services are based on primary health care principles
- Knowing the background of health needs and perspectives of patients and population (internal and external)
- Knowing the background of its collaborative team members: their professional preparation, identity, and unique contributions
- Demonstrating how it accomplishes organizational goals or vision

How Will Staff Work With Patients and Families?

- By placing patient's and family's needs first with a patient-focused approach
- By involving patients and families as members of a collaborative practice team
- By making effective communication a priority

What Are the Standards of the Work Unit?

- Staff members adhere to professional accountability practice according to standards of practice and codes of ethics
- Staff members practise within a culture of safety
- The work unit integrates evidence-informed best practices
- Staff members work collaboratively with all members of the health care team

What Are the Key Values?

- Creating and maintaining a healthy practice environment
- Recognizing social justice issues
- Supporting relational practice
- Being self-aware, motivated, and accountable
- Supporting a learning environment
- Providing culturally safe care

of care that is reviewed and revised to meet the changing needs of the client” (RNAO, 2010b, p. 61). It refers to continuity of information or knowledge, continuity of relationships between a patient and one or more health care providers over time, and continuity of management of care across organizational boundaries (Smith et al., 2006). In the choice of nursing care delivery models, it is important to consider how nurses ensure that a patient’s plan of care is as consistent as possible. As change occurs in health care delivery and nursing practice, new care delivery models are evolving (Kimball et al., 2007; LeClerc et al., 2008). In the current context, a patient care model known as the *collaborative practice model*, which includes nurses and others, incorporates some of the features of earlier models.

Nursing care delivery models of today entail higher staff ratios of unregulated care providers (UCPs) in many settings of practice, including home care, institutional acute care, and residential long-term care. The title of the UCP typifies the role of providing front-line personal and delegated care to increasing numbers of patients across different health care settings in Canada. UCP practice is not defined by qualifications or established standards. The title of the role differs from province to province, as does its requirement for training or educational programs. In British Columbia, for example, UCPs are referred to as health care assistants (HCAs) and they are required to take a preparatory six-month certification program offered in public and private postsecondary educational institutions. This is not the case in all provinces; for example, in Alberta, UCPs are not required to have educational preparation, and they are referred to as *patient care attendants* (PCAs).

Traditional Models of Care. Terms that describe models of care that have been present over the past century include *functional nursing*, *team nursing*, and *primary care*. These models have existed primarily in institutional settings, and elements of them may be seen in practice today. Functional nursing became popular during World War II in response to a nursing shortage, where nurses focused on tasks as opposed to assuming responsibilities for a group of patients. The disadvantages of functional nursing are problems with continuity of care, absence of a holistic view of patients, and the possibility that care will become mechanical and fragmented (Dadich, 2003). Despite the critique of functional nursing, you may see aspects of this model in practice today—for example, when a nurse assumes sole responsibility for all patient medications in a long-term care setting.

Team nursing developed in response to the nursing shortage after World War II (Marriner Tomey, 2004). It involves the coordinated delivery of nursing care by various staff members. A registered nurse (RN) leads a team of other RNs, registered psychiatric nurses (RPNs), licensed practical nurses (LPNs), UCPs, or a combination of these professionals. The task orientation of the model in the past and the fact that nurses do not always interact with the same patients each day can result in a lack of continuity of care. An advantage of team nursing is the collaborative style that encourages each member of the team to help the other members. This model has a high level of autonomy for the team leader and is an example of decision making at a clinical level (Marriner Tomey, 2004). Elements of this former team nursing model may be present in emerging models of collaborative practice with the evolution to more patient care focused on participatory relationships.

The **primary nursing** model aimed to place RNs at patients’ bedsides and improve nursing accountability for patient outcomes and relationships among staff (Ritter-Teitel, 2002).

Primary nursing supports a philosophy of strong nurse–patient relationships. Primary nursing maintains continuity of care across shifts, days, or visits. It can be applied in any health care setting. When a primary nurse is off duty, other team members, including RPNs, LPNs, or other RNs, follow the care plan. If differences in opinion occur, associate and primary nurses collaborate to redefine the plan as necessary. The strengths of this model may also be realized in new models of care that extend primary care models to fit the current health care delivery system and emphasize collaborative relationships, evidence-informed practice, and continuity of care (Jost et al., 2010; LeClerc et al., 2008).

Emerging Models of Care. Emerging models of care emphasize the role of the RN in providing a continuity of care to patients across settings. Another goal of emerging models of care is to emphasize and acknowledge that the skill and knowledge of the RN is needed in patient care as well as providing coordination and management of teams. The **case management** model is one that emphasizes the coordination of an array of health services and links them to patients and their families while streamlining costs and maintaining quality (Dadich, 2003). The term *case manager* has been criticized because patients and families are not “cases” to be managed (Smith et al., 2006). Case management, as it has evolved, is “a collaborative process which assesses, plans, implements, coordinates, monitors, and evaluates the options and services required to meet an individual’s health needs, using communications and available resources to promote quality, cost-effective outcomes” (Case Management Society of America, 2008). Clinicians, as individuals or in teams, care for patients with specific conditions and associated care needs (e.g., patients with complex nursing and medical problems) and are usually held accountable for quality and cost management. Many case managers use critical pathways, or “care maps,” which are multidisciplinary treatment plans for patients with specific case types (see Chapter 12). The plans help in the delivery of timely, coordinated care.

Roles of case managers vary across health care settings, including long-term care, home care, community mental health, and acute care institutions, and these professionals increasingly coordinate and integrate care across settings. Roles and responsibilities of case managers across settings include clinical expert, advocate, educator, facilitator, negotiator, manager, and researcher (Smith et al., 2006).

The collaborative practice model is increasingly used by **intraprofessional nursing teams** (teams whose members provide nursing care) and by other health care providers who are members of the **interprofessional team**. A call for interprofessional team and collaborative practice development has been sounded across Canada because this model is viewed as the way to ensure that all professionals and providers can practise to the full potential of their role and competencies. Collaborative practice is therefore also the best way to ensure that health human resources are used most effectively during a time of shortage in the achievement of quality care and population health outcomes. It is important for students in nursing and other professional health care programs to learn the competencies associated with collaborative practice during their educational programs. As a student, you are an integral member of both nursing and interprofessional teams that cross health care settings, including acute care, mental health care, community and home care, and public and population health care (RNAO, 2010b). One of the first and most important

responsibilities is to learn about the roles and responsibilities of other team members. Central to the collaborative practice model are the patient, family, and population as full participants in care or service delivery. Nurse leaders in the Vancouver Coastal Health Authority (2007) launched an important initiative to support the shift in thinking required for collaborative practice among teams of nurses and health care providers and across disciplines. This initiative provides opportunities for RNs, LPNs, UCPs, and members of other health care professions to learn from each other and to understand and respect their different roles and responsibilities. It also provides educational sessions in which team members learn about the competencies necessary in collaborative practice on a day-to-day basis in the work setting.

The RNAO (2010b) developed evidence-informed **best practice guidelines** for collaborative practice. These guidelines show how teamwork and collaborative practice can be supported at individual, team, organizational, and system levels of nursing practice. These guidelines are comprehensive and indicate the need for transformational leadership to support a culture of teamwork and collaboration. Thus, a collaborative practice model potentially incorporates the best of other care delivery models, including team, primary, and case management models previously discussed. It is important for students and entry-level nurses to acquire competencies that promote collaboration among teams as identified in Box 10-5.

Nurses are well situated to provide leadership for collaborative practice in many health care settings. One example may be found in the home care setting, in which nurses work

closely with UCPs, who provide a large amount of the continuous day-to-day care for patients who have been discharged from hospitals after undergoing surgery or who have chronic illnesses and disabilities. UCPs must have opportunities to meet and communicate regularly with the nurses and other professionals involved in the care of the patients, to ensure that they understand the patient situation and receive support for the challenges they face in providing care. Nurses can also aid UCPs by providing education and other supports so that they are able to contribute to best practices in important areas such as safety, emotional support, and wound healing. In this way, UCPs are recognized and valued for their role, and the continuity of care to a single patient or family is supported by UCPs, nurses, and other health care providers. Nurses who are employed in long-term or residential care settings may also provide leadership for collaborative practice by ensuring opportunities for communication and learning among professionals involved in teams or systems of care.

Home care delivery also often includes social workers, physicians, nutritionists, physiotherapists, and other health care providers, as well as nurses and UCPs. At the centre of the collaborative practice model is the patient and family; research is just beginning into how health care providers and other caregivers include patients as part of the team or the social network of care (Cott et al., 2008). A nurse in home care or another practice setting is well situated to provide leadership for collaborative practice by providing opportunities for patients and families to meet with caregivers and by ensuring that the patient's voice is heard in his or her care planning.

Health care in the twenty-first century will require nurses to work with other members of the health care team and collaborate with other community members, agencies, and organizations outside of the health sector. Intersectoral collaboration is a principle of primary health care, requiring nurses and others to develop skills in engaging with others to influence health in the broadest way possible. This ability to collaborate across professions and organizations requires the development of competencies in communication and conflict resolution, team functioning, and collaborative leadership that starts with a deep understanding of one's own professional role and contribution, as well as the appreciation of others' contributions (Canadian Interprofessional Health Collaborative [CIHC], 2011). Implementing collaborative practice among professionals requires that no one professional group dominates, leadership is shared, and differences in knowledge and contributions are understood and respected. Educators and practice leaders in the health professions are working to envision and develop education strategies to prepare students to graduate with interprofessional competencies.

Decision Making

One of the most important recommendations to achieve healthy practice environments is that staff at all levels be involved in decision making about nursing practice. It is of utmost importance that the voice and decisions of nurses who are providing care are valued and acted upon. Of equal importance is that the most senior nurse in the organization be included in the executive decision-making level of the organizations and agencies, including those responsible for the delivery of home care, mental health care, public health care, or hospital care. The nurse executive supports managers and staff by creating a management structure that helps achieve organizational goals and provides support for participatory

RNAO Best Practice Guideline: Nursing Collaborative Practice

Guideline 1.4: Nursing teams establish clear processes and structures that promote collaboration and teamwork that leads to quality work environments and outcomes for patients by

- Establishing processes for conflict resolution and problem solving
- Establishing processes to develop, achieve, and evaluate team performance
- Developing systems and processes to recognize and reward success
- Incorporating nonhierarchical, democratic working practices to validate all contributions from team members
- Incorporating processes that support continuity of care with patients to enhance staff satisfaction, staff self-worth, and patient satisfaction
- Developing and implementing processes that clarify their understanding of the unique and shared aspects of roles within the teams
- Ensuring that the composition of the team is adequate to achieve their goals and meet their responsibilities to the needs of the patient population
- Establishing processes for decision making for a variety of circumstances such as
 - Emergencies
 - Day-to-day functioning
 - Long-term planning
 - Policy development
 - Care planning

decision making and collaborative practice models. With a vision for nursing established, the manager helps staff realize that vision.

Decentralized or participatory management, in which decision making occurs at the staff level, is a vital part of a healthy work environment and effective health care organization; however, it has not been achieved to the extent needed. The advantage of this structure is that managers and staff are actively involved in shaping an organization's identity and determining success. Decentralized management requires workers to be empowered to accept greater responsibility for the quality of patient care (Ellis & Hartley, 2005). A decentralized structure has the best potential to lead to positive outcomes, such as increased collaboration among staff, best practice implementation, and patient satisfaction (Table 10-1).

The nurse manager is crucial for the successful functioning of nursing units and systems. Figure 10-2 illustrates the responsibilities and competencies of nurse managers, including

supervising, planning, scheduling, and staffing, as situated within a framework of leadership competencies.

Nurse managers must enable decision making by the professionals who are most involved and must encourage inclusion rather than exclusion of staff (RNs, RPNs, LPNs, UCPs, unit administrators, and secretaries). Nurse managers of today are making crucial decisions about the nursing care delivery models and staff mix that will best meet patient needs and promote optimum health outcomes. Three national nursing groups representing RNs, LPNs, and RPNs have worked with leading nurse researchers, including Dr. Linda McGillis Hall, to identify evidence-informed guiding principles for making staff mix decisions for quality care (Box 10-6). These principles can be realized only through collaborative nursing leadership, with values of inclusiveness and evidence-informed decisions about nursing care delivery models.

Nurses must develop skills and knowledge to exercise responsibility, autonomy, authority, and accountability in

► **TABLE 10-1** Examples of Management Structures

Structural Approach

Centralized management

Decentralized/participatory management

Matrix

Characteristics

A single administrator leads the organization, and directors oversee departments or programs. Decisions are made by the leader and directors, with little staff input. Managers have minimal responsibility or accountability for operation of nursing unit. Staff do not feel involved in care processes, and collaborative practice is not supported.

Staff members with the most knowledge about an issue participate in decision making. Structures such as professional practice councils exist to promote collaboration and decision making. Managers responsible for nursing care units or community programs often have accountability and responsibility for staffing decisions, budget, and day-to-day management of work unit.

Traditional units are reorganized into business units. Staff may report to several managers—such as one with responsibility for professional practice (e.g., nursing) and another with responsibility for a specific program (e.g., child and family health)—who may be from a variety of professional practice backgrounds.

► BOX 10-6

Five Guiding Principles for Staff Mix Decision Making

- Decisions concerning staff mix respond to clients' health care needs and enable the delivery of safe, competent, ethical, quality, evidence-informed care in the context of professional standards and staff competencies.
- Decision making regarding staff mix is guided by nursing care delivery models based on the best evidence related to (1) client, staff, and organizational factors influencing quality care and work environments, and (2) client, staff, and organizational outcomes.
- Staff mix decision making is supported by the organizational structure, mission, and vision and by all levels of leadership in the organization.
- Direct care nursing staff and nursing management are engaged in decision making about the staff mix.
- Information and knowledge management systems support effective staff mix decision making.

Source: Canadian Nurses Association. (March, 2012). Staff mix decision-making framework for quality nursing care. Ottawa: Author.

order to participate fully in organizational decision making and collaborative practice (Anders & Hawkins, 2006).

Responsibility refers to the duties and activities that an individual is employed to perform. A professional nurse's responsibilities in a given role are outlined in a position description of the nurse's duties in patient care and of participation as a member of the nursing team. Managers must be sure that staff members understand their responsibilities, particularly during change. For example, when hospitals restructure and patient care delivery models change, the manager must clearly define the nurse's role within the new care delivery model. If decentralized decision making is in place, professional staff can help shape the new nurse role. All nurses are responsible for knowing their role in developing competencies.

Autonomy is the freedom of choice and responsibility for choices (Marriner Tomey, 2004). With autonomy, a nurse can make independent decisions about patient care according to the role and scope of practice. Innovation by nurses, increased productivity, higher employer retention of nurses, and greater patient satisfaction are results of autonomy in nursing practice (Estabrooks et al., 2005; Health Canada, 2002; Hicks, 2003).

Authority to act is the right to act in areas in which a nurse has been given and accepts responsibility according to legislation, standards, and the code of ethics governing the professional practice of nursing. Nurses have authority to act and to question actions concerning the practice of other professionals in relation to this scope of responsibility. For example, a nurse who as a case manager finds that the nursing team did not follow a discharge teaching plan for an assigned patient has the authority to consult with other nurses to learn why the plan was not followed. The nurse as case manager has accepted responsibility for the care of a group of patients and therefore has the final authority in selecting the best course of action for the patient's care, while collaborating with others to ensure quality outcomes.

Accountability means being answerable for one's actions. It means that as a nurse, you accept the commitment to provide excellent patient care and the responsibility for the outcomes of actions in providing that care (Anders & Hawkins, 2006). A

nurse is accountable for patients' outcomes. In the example just described, the nurse as case manager is accountable for the patient's health outcomes by ensuring a continuity of care across hospitalization and home care.

A successful decentralized nursing unit exercises the four elements of decision making: responsibility, autonomy, authority, and accountability. The staff must meet routinely to discuss how to maintain equality and balance in these elements. Individuals should be comfortable in expressing differences in opinion and challenging the status quo, while understanding their own responsibility, autonomy, authority, and accountability.

Supporting Staff Involvement. In decentralized decision-making structures, all staff members actively participate in unit or agency activities (Figure 10-3). Staff members benefit from the knowledge and skills of the entire team. If the staff members value knowledge and their colleagues' contributions, patient care improves. The nursing manager supports staff involvement through the following approaches.

Establishment of Nursing Practice or Professional Shared Governance Councils. Chaired by senior clinical staff, these councils are empowered to maintain care standards for nursing practice (Gokenbach, 2007). The councils review and establish standards of care, develop policy and procedures, resolve patient satisfaction issues, or develop new documentation tools. Mechanisms are established to empower all staff to contribute input on practice issues. Managers might not sit on the council, but they receive progress reports. The types of work in the nursing unit is what determines council membership. Professionals from other disciplines (e.g., pharmacy, respiratory therapy, social work, medicine, or clinical nutrition) might participate in these councils. Professional practice councils can advocate for resources and conditions necessary for healthy practice environments and safety.

Interprofessional Collaboration. As previously described, collaborative practice among professionals from different disciplines is essential to ensuring that health human resources are used in the best possible way. Whenever systems or programs are redesigned, interprofessional involvement is crucial because most health care processes involve more than one discipline (CNA, 2003). Nurses must recognize the importance of prompt referrals and timely communication with other care

providers. Inclusion of professionals from various disciplines in practice projects, in-service programs, conferences, and staff meetings fosters interprofessional collaboration. Learning the skills and knowledge for interprofessional practice begins in nursing education, and student nurses are encouraged to seek practicum and other opportunities that allow them to work with other professionals and providers and articulate nursing's unique role and contribution to practice.

Staff Communication. Communication with staff is one of the manager's greatest challenges, especially in a large work group in which change is constant. It is difficult to ensure that all staff members receive the correct messages. In the current health care environment, staff quickly become uneasy and distrusting if they fail to hear about planned changes in their work unit. A manager cannot be responsible for all communication but can use several approaches to communicate quickly and accurately with all staff: increasing presence on work units, circulating newsletters, posting minutes of committee meetings, and using list servers and e-mail. Of most importance is that staff members have the opportunity to meet and to discuss issues pertinent to their role and ability to provide care. Professional councils must be valued and invited to provide advice on emerging issues.

Developing a Learning Organization. Nurses must continually update their knowledge and incorporate best practices that are evidence informed (Cullum et al., 2008). Leaders and managers are challenged to develop the conditions for learning to flourish in what has been described as a *learning organization* (Senge, 2006). In learning organizations, many forms of knowledge are shared. Leadership strategies are needed to help nurses incorporate evidence-informed best practice guidelines into their nursing practice. These strategies include "support, role-modelling commitment to best practices and reinforcing organizational policies and goals consistent with evidence based care" (Gifford et al., 2006, p. 73). Technology such as Web-based applications and social media will continue to transform how we learn and communicate in organizations requiring attention to ethical issues such as privacy and confidentiality, as well as the power of the media for influencing change in systems (Aylott, 2011; Mostaghimi & Crotty, 2011; Smith, 2012). These influences will require both vigilance and ethical consideration of managers and leaders.

Clinical Care Coordination

As a nursing student, you develop the skills necessary to ensure timely and effective patient care. At first, you may have only one patient, but eventually you will coordinate the care of groups of patients. Clinical care coordination includes decision making, priority setting, use of organizational skills and resources, time management, and evaluation.

Clinical Decisions. Leadership and decision-making skills are required as the nurse engages in the complex interactions—collaboration, negotiation, conflict resolution, and delegation—necessary to elicit the involvement of other people. You learn to value and practise patient centredness in every interaction. You will adopt a critical thinking approach, applying understanding of patients' perspectives, your knowledge, evidence-informed best practice guidelines, and experience to the decision-making process (see Chapter 11).

Priority Setting. You must establish priorities of care as they relate to actions taken to meet patients' needs. This is particularly important in caring for groups of patients with health challenges involving immediate needs and actions to be

taken. Hendry and Walker (2004) classified patient problems in three priority levels on the basis of the time frame in which you must act:

- *High (first-order) priority:* An immediate threat to a patient's survival or safety, such as a physiological episode of obstructed airway, loss of consciousness, injury, or an anxiety attack.
- *Intermediate (second-order) priority:* Nonemergency, non-life-threatening actual or potential needs that the patient and family members are experiencing, such as anticipating teaching needs of patients with regard to a new drug, wound care, or measures to decrease falls among older adults.
- *Low (third-order) priority:* Actual or potential problems that may or may not be directly related to the acute phase of the patient's health challenge. This means that they are not as time sensitive; however, they should be viewed as important to the health outcomes over the slightly longer term. Examples include promoting family members' understanding of a diabetic diet or other aspects of chronic illness management.

Many patients can have all three types of priorities, which requires you to use careful judgement in choosing a course of action. First-order priority needs require your immediate attention and, most often, immediate assistance in meeting these needs. Setting priorities also requires that you know the priority needs of each patient, assessing each patient's needs as soon as possible, including the patient and family determination of priorities, and addressing needs in a timely manner (Wywiałowski, 2004). You consider resources, recognize that priority needs can change, and use your time wisely.

Time Management. Changes in health care delivery and increasing complexity in all settings of care can create time management challenges for nurses as they work to meet patients' needs (Marriner Tomey, 2004). Time management skills can help you manage stress. These skills include reflecting on how you use time, planning effectively, and being aware of competing priorities. Because of the complexity of practice, nurses are often required to juggle priorities and respond to multiple demands on their time. It is therefore most important to track these demands and ensure that resources are in place that allow you to focus on priorities in a timely manner. Technology such as e-mail correspondence has increased demands on nurses' time and often require immediate responses. It is therefore important for you to realize and reflect on the impact of technology and other forces and to acquire the ability to set limits and refuse demands that are unreasonable.

Evaluation. Evaluation is one of the most important aspects of clinical care coordination. Evaluation is an ongoing process that provides focus and direction for each phase of nursing care. Once you begin to provide care, you should also learn to immediately evaluate its effectiveness and the patient's response. In the evaluation process, you compare expected patient outcomes with actual outcomes. For example, a clinic nurse assesses a diabetic patient's foot ulcer to determine whether healing is progressing and expected outcomes are met. Evaluation reveals the need to revise approaches to care and introduce new therapies. Focusing on evaluation of a patient's progress and outcomes, rather than on tasks, lessens the chance of distraction. You learn to keep the patient at the centre of the care by asking the patient for his or her ideas and evaluation of how he or she is experiencing the care plan.

Delegation. Changes in staff mix have resulted in more UCPs delivering care to patients (CNA, 2008; McGillis Hall,

2004). In the new working environment, a nurse must understand the evolving role of nursing and delegated care responsibilities in order to ensure the safety and quality of nursing care delivery. **Delegation** refers to the transferring of responsibility for the performance of an activity or task while retaining accountability for the outcome (College of Registered Nurses of British Columbia, 2005). Delegated tasks are those that are outside of the role description of the UCP. As a student, you will work with teams of nurses and UCPs during your practica in many health care settings, including home care, residential care, community health care, and acute care settings. As you develop in your role, it is important to learn about the roles and scopes of practice of UCPs in different practice settings. You will learn about how your role relates to that of the UCP and how the principles of delegation are applied in practice. Students and nurses also have access to valuable resources such as nursing practice consultants and practice guidelines to assist them in making complex decisions about delegation. The nurse may also assume responsibility for the education, supervision, and support of UCPs as they perform delegated nursing activities (Box 10-7).

Provincial regulations define the scope of an RN's practice, including activities that only RNs can perform (e.g., patient assessment and planning care). Although most provinces identify the delegation and supervision of work as an RN's responsibility, each province addresses the specifics of delegation differently. In Ontario, British Columbia, and Alberta, for example, legislation that applies to all regulated health care

providers identifies specific tasks or activities that can be performed by only certain providers. In British Columbia, these authorized tasks are known as *reserved acts*; in Ontario, they are called *controlled acts*; and in Alberta, they are known as *restricted activities*. UCPs are not allowed to perform actions authorized for RNs unless those actions have been properly delegated by an RN and only if they are within the UCP's job description and employer policy (Sorrentino, 2009).

An institution's policies, procedures, and job descriptions for UCPs provide specific guidelines regarding which tasks or activities can be delegated. The job description should specify any required education and the types of tasks UCPs can perform, either independently or under an RN's direct supervision. Institutional policy helps in defining the amount of training required of UCPs while they are employed. Procedures specify who is qualified to perform a given nursing procedure, whether supervision is necessary, and the type of reporting required. Job descriptions, policies, and procedures should comply with provincial laws and regulations. Nurses should have a means of accessing policies easily or have supervisory staff who can inform them about the UCP's job duties.

Effective delegation requires trust between the RN and UCPs. It also requires constant communication: sending clear messages and listening so that all participants understand expectations regarding patient care. An RN should provide clear instructions when delegating tasks. These instructions may initially focus on the procedure itself, as well as on the unique needs of the patient. As the RN becomes more familiar with a staff member's scope of practice, trust builds and fewer instructions may be needed, but clarification of patients' specific needs is always necessary.

A key step in delegation is evaluation of the staff member's performance and the patient's outcomes. When UCPs do a good job, it is important to provide praise and recognition. If the staff member's performance is unsatisfactory, the RN must give constructive feedback, specifically discussing mistakes and how they could have been avoided. Giving feedback in private in a professional manner preserves the staff member's dignity. A UCP may fail to meet expectations because of inadequate training or assignment of too many tasks. The RN may need to review or demonstrate a procedure with staff or schedule additional training with the education department. The delegation of too many tasks might be a nursing practice issue. All staff should discuss delegation on their unit because UCPs may need help in learning how to prioritize and RNs may need to ensure that they are not overdelegating.

A few tips for nurses on appropriate delegation (College of Registered Nurses of British Columbia, 2006; Keeling et al., 2000) follow:

- *Assess the knowledge and skills of the delegate.* Nurses should determine what the UCP knows and what he or she can do by asking open-ended questions that will elicit conversation and details; for example, "Can you tell me what you would observe in Mr. S when you visit him today that would alert you to call me immediately?"
- *Match tasks to the delegate's skills.* Nurses need to know what skills are included in the UCP training program at their facility and to determine whether personnel have learned critical thinking skills, such as knowing the difference between normal clinical findings and changes to report.
- *Communicate clearly.* Nurses should provide unambiguous directions by describing a task, the desired outcome, and the time period for completion of the task. Rather than

► BOX 10-7 The Five Rights of Delegation

Right Task

The right task is one that can be delegated for a specific patient, such as tasks that are repetitive, require little supervision, and are relatively noninvasive (bathing, toileting, feeding, some oral medication administration, positioning, and assisting with mobility).

Right Circumstances

The appropriate patient setting, available resources, and other relevant factors are considered. In an acute care setting, patients' conditions can change quickly. Good clinical decision making is needed to determine what to delegate.

Right Person

The right person (e.g., the nurse) is delegating the right tasks to the right person (e.g., the UCP) to be performed on the right person (the correct patient).

Right Direction or Communication

A clear, concise description of the task, including its objective, limits, and expectations, is given. Communication must be ongoing between RN and UCPs during a shift of care.

Right Supervision

Appropriate monitoring, evaluation, intervention as needed, and feedback are provided. UCPs should feel comfortable asking questions and seeking assistance.

Modified from National Council of State Boards of Nursing. (1995).

Delegation: Concepts and decision-making process. Chicago: Author; National Council of State Boards of Nursing. (1997). *The five rights of delegation.* Chicago: Author; and American Nurses Association (ANA) and National Council State Boards of Nursing. (2006). *Joint statement on delegation.* Retrieved from http://www.ncsbn.org/pdfs/joint_statement.pdf.

giving instructions through another staff member, nurses should make the delegate feel part of the team. For example, "I'd like you to help me by getting Mr. Floyd up to ambulate before lunch. Be sure to check his blood pressure before he stands and write your finding on the graphic sheet. Okay?"

- *Listen attentively.* Nurses should listen to the UCP's responses as they give directions. Is the UCP comfortable asking questions or requesting clarification? Nurses need to be especially attentive if the UCP has a deadline assigned by another nurse and to help sort out priorities.
- *Provide feedback.* Nurses should give feedback about performance, regardless of outcome. They must tell the person about a job well done or, if an outcome is undesirable, find a private place to discuss what occurred, any miscommunication, and how to achieve a better outcome in the future.

Quality Care and Patient Safety

As discussed throughout this chapter, safe and high-quality care is delivered when leadership, staffing models, and collaborative practice are in place to support it. Studies reveal that high-quality practice environments produce better patient outcomes and more satisfied patients and staff (Aiken et al., 2001, 2002; CNA, 2008; Tourangeau et al., 2002). Initiatives such as the College of Nurses of Ontario's (2004) *Quality Assurance Practice Consultation Program* and the Registered Nurses Association of British Columbia's (2003) *Quality Practice Environment Program* assess organizational attributes that enhance practice. The assessment is voluntary, but response by health care agencies is encouraging.

Organizational programs such as total quality management (TQM) and continuous quality improvement (CQI) were developed to encourage staff to reflect on how to improve work. In quality management, the patient's or customer's definition of quality is recognized (Wendt & Vale, 2003). Most organizations have moved away from programs identified as TQM or CQI and focus on the more generic and pervasive concept of **quality improvement (QI)**, defined by the Canadian Council on Health Services Accreditation (2003) as "an organizational philosophy that seeks to meet clients' needs and exceed their expectations by using a structured process that selectively identifies and improves all aspects of service" (p. 1). This council describes quality as responsiveness, system competency, patient or community focus, and work life. QI focuses on improving organizational performance related to processes.

Quality in Nursing Practice

Quality Defined. Standards or guidelines define the meaning of quality. For example, to judge whether rehabilitation has been delayed, a standard of when rehabilitation should begin must exist. Quality of care in nursing practice is not arbitrarily defined. A definition of quality begins with the mission, vision, philosophy, and values of the nursing department. These statements define how all nurses within an organization are to perform and which services must be provided. Written values give direction for professional standards and care guidelines that lead to positive patient outcomes.

Professional Standards. Professional standards are authoritative statements used by the profession in describing the responsibilities for which its practitioners are accountable (Peters, 1995). They include the policies and position descriptions that identify performance expectations within an

organization. Standards are an organization's interpretation of the professional's competency. The adherence to professional standards is measured through professional outcomes.

Care and Best Practice Guidelines. Care guidelines encompass best practice guidelines, which are statements to assist in providing care according to the best evidence available (RNAO, 2003). Guidelines can be developed by single disciplines or can be multidisciplinary in focus. Examples of nursing practice guidelines are found on the RNAO Web site encompassing some of the examples referred to in this chapter, including wound care and prevention of falls. The effectiveness of nursing practice is measured through patient outcomes and the accumulation of evidence (Graham & Harrison, 2008).

Nurse-Sensitive Outcomes. Outcomes are conditions to be achieved as a result of care. It is important that the outcomes selected to measure the effectiveness of nursing care are related to the work that nurses do. A **nurse-sensitive outcome** reveals whether interventions are effective, whether patients progress, how well standards are being met, and whether changes are necessary. Examples of outcomes related to the implementation of best practice guidelines may include incidence of pressure sores, falls in elderly patients, and hypertension control measures.

To judge whether standards of care are met, processes and outcomes are measured. For example, a staff measures its success in implementing a new process of diabetes instruction and also measures the outcome: Can patients administer insulin correctly? When selecting quality indicators, teams should consider processes and related outcomes that are most likely to improve nursing practice. Processes to improve may include the following:

- A weak process that is causing problems (e.g., poor pain management for patients with cancer who are at home)
- A stable process that is adequate but can improve (e.g., access to education and support for people with diabetes in rural communities)
- A process linked to negative outcomes (e.g., care of intravenous access sites with the occurrence of phlebitis)

Building a Culture of Safety

Patient safety has been recognized as a crucial component of health care delivery. The Canadian Patient Safety Institute (2009) defined patient safety as "the reduction and mitigation of unsafe acts within the health care system, as well as through the use of best practices shown to lead to optimal patient safety." Issues such as staff shortages, new technology, and other demands on health care systems have prompted a re-examination of how errors and adverse events for patients can be prevented. Increasingly, the emphasis is on enabling health care providers to communicate effectively and to acknowledge and receive timely assistance for errors. This assistance includes the education of nursing and other health care students to view mistakes as learning, to know and prevent conditions that lead to unsafe practices, and to develop the **competencies for safe practice** (Canadian Association of Schools of Nursing, 2006; Davidson et al., 2006). The Canadian Patient Safety Institute (2009) identified seven core domains of abilities for all health care providers, including their contributions to developing a culture of patient safety as a most important foundation (Box 10-8).

Coming Full Circle: Leadership for a High-Quality Work Life and High-Quality Health Care. Leaders and managers at all levels of health care organizations must do

► BOX 10-8 The Safety Competencies

Domain 1: “Creating a Culture of Patient Safety” (<http://www.patientsafetyinstitute.ca/English/toolsResources/safetyCompetencies/Documents/Safety%20Competencies.pdf>)

Health care professionals must be enabled to contribute to health care organizations, large or small, in ways that promote patient safety in their structure and function. Content in this domain could include but is not limited to the following aspects:

- Understanding of patient safety concepts, epidemiology, and basic theories
- Awareness of health care error
- Promotion of a systems approach to care and safety
- Promotion of staff empowerment to resolve unsafe situations
- Role modelling and demonstration of a commitment to leadership in safe practice
- Ensuring feedback on safety issues
- Integration of safe practices into daily activities
- Commitment to communication, teamwork, and quality
- Reporting of adverse events
- Commitment to a just, nonpunitive culture (Canadian Patient Safety Institute, 2009)

what they can to improve the quality of work life in health care in order to ensure patient safety and quality health care; evidence and awareness of this need are growing. A forward thinking and exciting partnership of 10 leading health care organizations in Canada, including the CNA and the Canadian Council on Health Services Accreditation (now known as “Accreditation Canada”), have formed the Quality Worklife-Quality Healthcare Collaborative (QWQHC) with the mandate and a guiding conceptual framework to “improve the health of health workplaces” (QWQHC, n.d.) The foundational belief of the QWQHC is that “a fundamental way to better healthcare is through healthier health care workplaces; it is unacceptable to work in, receive care in, govern, manage and fund unhealthy workplaces” (QWQHC, n.d.).

Nurse fatigue has been identified as a current factor in patient safety requiring the attention of governments, organizations, and individual nurses (CNA & RNAO, 2010). Recommended solutions to the problem based on research include the role of nurse managers in instituting fatigue management policies and programs. These measures require significant changes in the workplace and collaboration with nursing unions and nursing education programs. Measures to be considered include rest and sleep policies, as well as reform of scheduling practices (CNA & RNAO, 2010). Nurse managers have significant responsibilities in implementing these solutions, and they provide leadership in this area to make a difference to both the quality of nurses’ work lives and patient safety outcomes.

Leadership Skills for Nursing Students

Nursing students prepare for leadership roles. This does not mean you must quickly learn how to lead a nursing team; rather, you first learn to become an accountable and competent health care provider. Leadership development is ongoing throughout a career, and individual leadership styles are influenced from a variety of sources, including theories, best

Figure 10-4 The Donner-Wheeler Career Planning and Development Model **Source:** Waddell, J., Donner, G. J., & Wheeler, M. M. (2009). *Building your nursing career: A guide for students* (3rd ed., p. 2). Toronto: Elsevier Canada.

practices, mentors, role models, and experiences. You learn leadership by making good clinical decisions, advocating for public health and quality care, learning from mistakes, seeking guidance, engaging in collaborative practice with nursing teams and other professionals, seeking mentors, and striving to improve during each patient interaction. Recent research in Canada has indicated that mentorship components of new graduate transition programs are key to helping new graduate nurses become part of the nursing workforce (Baumann et al., 2011). Your nursing education program provides you with the opportunity to develop leadership competencies: advocacy, conflict management, collaborative practice, patient centredness, delegation, and evidence-informed decision making.

Career Development and Mentoring for Nursing Students

Nursing students have the opportunity to begin to envision their preferred career path early in their nursing education program. In fact, it is likely that students who do begin to plan their careers or “course of life work” are more likely to achieve their goals and develop personal and professional strengths that enable their future career satisfaction and success (Waddell et al., 2009). As you develop a career vision, you may identify opportunities that can further your development as a nurse leader, such as attending meetings of professional associations, presenting your work at student conferences, and finding a career coach or mentor (Cooper & Wheeler, 2010; Mata et al., 2010). Waddell et al. (2009) have developed the Career Planning and Development Model for students to use during their nursing education program (Figure 10-4). The model includes stages of planning that engages the student in learning about nursing realities and trends, developing a self-assessment, and creating a career vision and marketing approach. These authors contend that having a career vision is “perhaps the most

BOX 10-9

NURSING STORY

Leadership for Best Practices in Falls Prevention

Kaley Hart is a recently graduated RN working in a residential care facility. Ann Best, the nurse manager of the facility, is aware of Kaley's interest in leadership for best practices. As a fourth-year student, Kaley had completed a special project on falls prevention in the facility, using local statistics on falls and evidence-informed practice guidelines. Ann wishes to enroll the long-term care facility in the National Collaborative on Falls in Long-Term Care (RNAO, 2007b). This program requires the commitment of an improvement team consisting of five to seven staff members. Ann's vision is that the improvement team would be supported by the educational and research resources of this national program and by access to national experts in falls prevention. She sees this as an excellent opportunity for Kaley to be involved and to continue to develop her leadership skills in the areas of collaborative practice and best practices implementation.

At Ann's invitation, Kaley becomes involved with the quality improvement team, which also includes a nurse researcher from the university. Kaley begins her work by inspiring other nurses to become involved with the initiative, and she advocates for UCOs and other professionals to become members of the team in order to achieve a broad perspective on the changes required to prevent falls. She refers to the Canadian statistic that 50% of elderly residents in nursing homes fall every year (RNAO, 2007b), which results in a negative impact on their quality of life and increased costs to the health care system. Kaley inspires a vision of changes to be made in the interest of preventing falls and achieving the best possible health outcomes for the residents in the facility. She advocates for residents' and their families' involvement in the initiative

and seeks input from all patients and professionals as to how the learning sessions should take place, in order to promote engagement as a learning community.

As a member of the team, Kaley contributes her knowledge of the RNAO (2007a) *Falls Prevention Best Practices Guidelines* and helps develop a practical approach to identifying residents who are at risk for falls. Drawing on her knowledge of collaborative practice, Kaley ensures that other members, including the physiotherapist, UCP, recreation therapist, nutritionist, and housekeeping manager, are able to contribute their experiences and ideas about risk management and participate in the learning sessions. Kaley takes the opportunity to praise the contributions of diverse team members and to facilitate input and participation from the residents.

An evaluation of the quality improvement team reveals high levels of participation and interest within the facility. The experience of being involved in a national initiative has contributed to the capacity for best practices implementation and evidence-informed practice. Kaley has been inspired by the experience and has further developed her management and leadership competencies in the areas of inspiring a vision, leading change, facilitating collaborative practice, and developing respectful and supportive relationships among team members. She has worked with the nurse researcher at the local university to develop the plan for studying the impact of the changes on the incidence of falls, over time. Of most importance is that Kaley looks forward to the next opportunity to make a difference in the health outcomes of the residents through the exercise of progressive management and leadership initiatives.

forceful motivator for using your nursing practice placement and classroom experiences and your summer and part-time work opportunities to the fullest" (2009, p. 7).

Transformational leadership, including the concepts and competencies discussed in this chapter, is needed to shift the current culture of health care to achieve the vision of health care providers delivering high-quality health care, adopted by the collaborative. This means that nurses and other professionals working directly with patients and the mid-level managers have key roles to play in leading change. They must be inspired and supported through mentoring and by the implementation of leadership best practices guidelines and collaborative practice. Senior leaders must ensure adequate staffing and support for the culture of a healthy workplace. The way forward is to inspire lifelong learning at all levels of the organization and provide access and resources to education that enables staff to work with the patient and the patient's family at the centre of health care delivery and decision making.

Nurses working at all levels of organizations can contribute by making a commitment to this vision and being part of the change that is required to transform Canadian health care. Indeed, the CNA in its centenary year inspires the theme of leadership for a transformed Canadian health care system and calls for Canadian nurses to "be the change" required to sustain quality health care for all. As a student and as a qualified nurse, you have the opportunity and the challenge to effect positive change in nursing practice and Canadian health care (Box 10-9).

❖ KEY CONCEPTS

- A leader must set a vision or philosophy for a work unit, ensure appropriate staffing, mobilize staff and institutional resources to achieve objectives, motivate staff members to carry out their work, set standards of performance, and make the right decisions to achieve objectives.
- Management and leadership are related processes; both are essential to nursing practice and health care delivery.
- Healthy practice environments are essential to quality nurse and patient care outcomes.
- Transformational leadership that emphasizes relationships, trust, and vision plays a key role in ensuring healthy practice environments.
- An empowered nursing staff has decision-making authority to change how they practise.
- Nursing care delivery models vary by the responsibility of the RN in coordinating care delivery and the roles other staff members play in assisting with care.
- Continuity of nursing care can be compromised in total patient care delivery, functional nursing practice, and team nursing.
- Best practice guidelines are evidence informed and contain recommendations for developing and sustaining collaborative practice models and leadership.
- For decentralized decision making to succeed, staff members must be aware that they have the responsibility, authority, autonomy, and accountability for the care they give and the decisions they make.

- A nurse manager can foster decentralized decision making by establishing nursing practice committees, supporting collaborative practice, implementing quality improvement plans, and maintaining timely staff communication.
- Clinical care coordination involves accurate clinical decision making, establishing priorities, efficient organizational skills, appropriate use of resources and time management skills, and an ongoing evaluation of care activities.
- To promote an enriching professional environment, each member of a nursing work team is responsible for open, professional communication.
- Delegation involves transferring responsibility for performing an activity while retaining accountability for the outcome.
- When accomplished correctly, delegation can improve job efficiency and job enrichment.
- An important responsibility for the nurse who delegates nursing care is evaluation of the staff member's performance and patient outcomes.
- In a quality improvement-oriented environment, every staff member becomes involved in finding ways to improve or change work processes so as to promote patient safety and quality care outcomes.
- The QWQHC was developed to transform Canadian health care delivery systems.
- Nurses' **career development** involves planning and opportunities for mentorship.

✦ CRITICAL THINKING EXERCISES

1. John, an RN, is working with Tammy, a UCP, to manage care for five patients. John has completed morning assessments and rounds on the assigned patients and is giving Tammy directions for what she needs to do in the next hour. John says to Tammy, "Why don't you go to Room 415 and see what Mr. Thomas needs, and go to Room 418 to check if Mrs. Landry is doing all right." Based on what you know about delegation, were these appropriate or inappropriate delegations to Tammy? Provide a rationale for your answer.
2. You are a recently graduated RN working in a home care setting. The manager of the nursing program asks you to assist with the implementation of a collaborative practice model. She asks you to help her set the agenda for the first meeting to discuss the concept and principles of collaborative practice. What ideas and resources would you contribute to the agenda?
3. You have just received morning shift reports on your patients. You have been assigned the following patients:
 - A 52-year-old man who was admitted yesterday with a diagnosis of angina. He is scheduled for a cardiac stress test at 0900.
 - A 60-year-old woman who was transferred out of intensive care at 0630 today. She underwent uncomplicated coronary bypass surgery yesterday.
 - A 45-year-old man who experienced a myocardial infarction three days ago and is complaining of chest pain, which he rates as 5 on a scale of 0 to 10.
 - A 76-year-old woman who had a permanent pacemaker inserted yesterday and is complaining of incision pain, which she rates as 7 on a scale of 0 to 10.

Which one of these patients do you need to see first? Explain your answer.

✦ REVIEW QUESTIONS

1. Transformation leadership most fundamentally involves
 1. Developing charismatic and highly influential leaders
 2. Envisioning new systems of care to get work done
 3. Developing relationships and involving others in change
 4. Introducing research and innovation
2. Collaborative practice models aim to
 1. Improve delegation between staff
 2. Improve communication between staff
 3. Place the patient at the centre of care delivery
 4. Ensure that health care providers can cover for one another
3. The type of care management approach that coordinates and links health care services to patients and their families while streamlining costs and maintaining quality is
 1. Case management
 2. Total patient care
 3. Functional nursing
 4. Primary nursing
4. The type of management structure that has a potential for greater collaborative effort, increased competency of staff, and ultimately a greater sense of professional accomplishment and satisfaction is
 1. Case management
 2. Primary nursing
 3. Total patient care
 4. Decentralized
5. While administering medications, the nurse realizes she has given the wrong dose of medication to a patient. The nurse acts by completing an incident report and notifying the patient's physician. The nurse is exercising
 1. Authority
 2. Responsibility
 3. Accountability
 4. Decision making
6. A manager who wishes to improve patient safety in the health care organization should focus on
 1. Problem-solving committees
 2. Staffing models and ratios
 3. Systems for reporting mistakes
 4. Staff communication
7. A home care nurse is working with three UCPs who were recently hired and are new to their roles. For the first two weeks of their employment, the UCPs have been providing care for patients at home with complex wounds and caring for families in palliative care situations. The nurse believes in the principles of collaborative practice and wishes to support the UCPs in their development. An important first step would be to
 1. Provide an opportunity for the UCPs to talk about their experiences, questions, and roles
 2. Provide an educational session on palliative care
 3. Set up a mentoring system among the UCPs
 4. Discuss the role of the RN in home care

8. A patient is experiencing an anxiety attack. This is which priority nursing need for this patient?
 1. First-order priority
 2. Second-order priority
 3. Third-order priority

9. The nurse checks on a patient who was admitted to the hospital with pneumonia. He has been coughing profusely and has required nasotracheal suctioning. He has an intravenous infusion of antibiotics. He is febrile. The patient asks the nurse whether he can have a bath because he has been perspiring profusely. The nurse may delegate to the UCP working with her today the task of
 1. Assessing vital signs
 2. Changing intravenous dressing
 3. Nasotracheal suctioning
 4. Administering a bed bath

10. An example of a nurse-sensitive outcome based on best practice guidelines is
 1. Rates of emergency room readmission after postsurgical discharge
 2. Percentage of time it takes to count narcotics by nursing staff every shift
 3. Number of falls among residents in a long-term care setting
 4. Time it takes for a patient to be transported from the emergency department to an inpatient nursing unit

✦ RECOMMENDED WEB SITES

Academy of Canadian Executive Nurses (ACEN): <http://www.acen.ca>

This is an association of nurses in leadership positions across the spectrum of health services. ACEN activities support leadership, advocacy and policy initiatives, and mentorship for emerging nurse leaders and executives.

Accreditation Canada: <http://www.accreditation.ca/en/>

Accreditation Canada, formerly known as the Canadian Council on Health Services Accreditation, is a national, nonprofit, independent organization whose role is to help health services organizations, across Canada and internationally, examine and improve the quality of care and service they provide to their patients.

Canadian Association of Schools of Nursing (CASN): <http://www.casn.ca>

The Canadian Association of Schools of Nursing (CASN) is the national voice for nursing education, research, and scholarship and represents baccalaureate and graduate nursing programs across Canada.

Canadian Health Services Research Foundation: <http://www.chsrf.ca>

The Web site of the Canadian Health Services Research Foundation contains research resources for policymakers and for health system leaders and managers pertaining to staffing models, high-quality health work life, and high-quality health care.

Canadian Interprofessional Health Collaborative: <http://www.cihc.ca>

The Canadian Interprofessional Health Collaborative (CIHC) is made up of health organizations, health educators, researchers, health professionals, and students across Canada. This

collaborative shares best practices and advances knowledge in interprofessional practice and collaborative practice.

Canadian Nurses Association (CNA): <http://www.cna-nurses.ca/cna>

The CNA is a federation of 11 provincial and territorial nursing associations representing more than 120,000 RNs. The CNA's mission is to advance the quality of nursing in the interest of the public.

Canadian Nursing Students Association (CNSA): <http://www.cnsa.ca/>

The CNSA is the national voice of nursing students in Canada. For more than 30 years, the CNSA has represented the interests of nursing students to federal, provincial, and international governments and other nursing and health care organizations.

Canadian Patient Safety Institute: <http://www.patient-safetyinstitute.ca/>

The Canadian Patient Safety Institute (CPSI) is an independent not-for-profit corporation, operating collaboratively with health providers and organizations and with regulatory governments and bodies to build and advance a safer health care system for Canadians.

Donnerwheeler: <http://www.donnerwheeler.com>

This Web site includes information and resources for career development and mentoring, developed by Canadian nurse leaders Gail Donner and Mary Wheeler.

International Council of Nurses (ICN): <http://www.icn.ch/>

The ICN is a federation of national nurses' associations, representing nurses in more than 120 countries. Operated by nurses for nurses, ICN works to ensure quality nursing care for all patients, sound health policies globally, and the advancement of nursing knowledge.

Interprofessional Rural Program of BC (IRPbc): <http://www.irpbc.com/>

The IRPbc offers a unique opportunity for students from various health care provider programs to experience life and work in a rural community in British Columbia and to participate in a number of interprofessional team activities. The Web site offers access to a 10-minute film, *Learning Together in Rural Communities*, which highlights the voices of the students about their experiences.

Registered Nurses' Association of Ontario (RNAO): <http://www.rnao.org>

This Web site offers a complete and up-to-date inventory of best practice guidelines, including implementation and evaluation.

Quality Worklife-Quality Healthcare Collaborative (QWQHC): <http://www.qwqhc.ca/>

This Web site describes the national interprofessional coalition of health care leaders who work together to develop an integrated action-oriented strategy to transform the quality of work life for Canada's health care providers. According to the QWQHC, this strategy enables patient safety and high-quality patient care and system outcomes.

Critical Thinking in Nursing Practice

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by Donna M. Romyn, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Describe characteristics of a critical thinker.
- Describe the components of a critical thinking model for clinical decision making.
- Explain the relationship between clinical experience and critical thinking.
- Discuss critical thinking competencies used in nursing practice.
- Discuss the nurse's responsibility in making clinical decisions.
- Discuss the relationship of the nursing process to critical thinking.
- Discuss the critical thinking qualities used in clinical decision making.
- Explain how professional standards influence a nurse's clinical decisions.
- Describe how reflective journal writing promotes critical thinking.
- Discuss how concept maps can improve a nurse's ability to think critically.

key terms

Clinical decision-making process, p. 141
 Clinical inference, p. 145
 Concept map, p. 149

As a nurse, you will face many complex situations involving patients, family members, and other health care workers. To deal with these experiences effectively, you need to develop sound critical thinking skills so that you can approach each new problem involving a patient's care with open-mindedness, creativity, confidence, and wisdom. When a patient develops a new set of symptoms, asks you to provide comfort, or requires a procedure, it is important to think critically and make prudent clinical judgements so that the patient receives the best nursing care possible. Critical thinking is not a simple, step-by-step linear process that you can learn overnight. Your ability to think critically will increase as you gain experience and progress from novice to expert nurse (Benner, 1984). Critical thinking is central to professional nursing practice because it allows you to test and refine nursing approaches, learn from successes and failures, apply new knowledge (e.g., nursing research findings), and ensure holistic patient-centred care.

Critical Thinking Defined

Critical thinking is a complex phenomenon that can be defined as a process and as a set of skills. Most definitions of critical thinking emphasize the use of logic and reasoning (Di Vito-Thomas, 2005) to make accurate clinical judgements and decisions. Accordingly, nurses recognize that an issue (e.g., patient problem or health-related concern) exists, analyze information about the issue (e.g., clinical data about the patient), evaluate information (e.g., review assumptions and evidence), and draw conclusions (Settersten & Lauver, 2004). In consultation with patients, nurses consider what is important in a situation, imagine and explore alternative solutions, consider ethical principles, and then make informed decisions about how to proceed. Consider the following case example:

Mr. Jacobs is a 58-year-old patient who had a radical prostatectomy for prostate cancer yesterday. His nurse, Tonya, finds him lying supine in bed with his arms extended along his sides and his hands clenched. When Tonya checks his surgical wound and drainage device, she notes that he winces when she gently palpates over the incisional area. She asks Mr. Jacobs when he last turned onto his side, and he responds, "Not since sometime last night." Tonya asks Mr. Jacobs if he is having incisional pain and he nods, saying, "It hurts too much to move." Tonya considers her observations and the information she has learned from the patient to determine that his pain is severe and his mobility is reduced because of it. Together, she and Mr. Jacobs decide to take action to relieve Mr. Jacob's pain so he can turn more frequently and begin to get out of bed to aid his recovery.

Critical thinking requires purposeful and reflective reasoning during which you examine ideas, assumptions and beliefs, principles, conclusions, and actions within the context of the situation (Brunt 2005a, 2005b). When you care for a patient, you begin to think critically by asking questions such as "What do I know about the patient's situation?" "How do I know it?" "What is the patient's situation now? How might it change?" "What else do I need to know to understand this situation better or improve it? How can I obtain that information?" "In what way will a specific therapy affect the patient?" "Are other options available?" By answering these questions, you are able to identify alternative solutions to resolve the patient's health-related concerns.

As you gain experience in nursing, avoid letting your thinking become routine or standardized. Instead, learn to look beyond the obvious in any clinical situation, explore the patient's unique responses to actual or potential health alterations, and recognize what actions are needed to benefit the patient. Over time, your experience with many patients will help you recognize patterns of behaviour (Tanner, 2006), see commonalities in signs and symptoms, and anticipate reactions to nursing interventions. Reflecting on your experiences will allow you to better anticipate patients' needs and recognize problems when they develop. It will also help you determine how the knowledge you gained working with one patient may be applicable to another patient's situation.

In Tonya's case, she knows that the patient is likely to have pain because the surgery was extensive. Her review of her observations and the patient's report of pain confirm that pain is a problem. Her options include giving Mr. Jacobs an analgesic and then waiting until it takes effect so that she can help him find a more comfortable position. Once his pain is less acute, Tonya might also ask Mr. Jacobs

whether he would like to try some relaxation exercises and mobilization techniques she learned while caring for another postoperative patient that may be effective in increasing his mobility.

You can begin to learn to think critically early in your practice. For example, as you learn about administering bed baths and other hygiene measures to your patients, take time to read this book and the nursing literature about the concept of comfort. What are the criteria for comfort? How do patients from other cultures perceive comfort? What are the many factors that promote comfort? Learning and thinking critically about the concept of comfort, in addition to acquiring the skills needed to provide comfort measures, prepares you to better anticipate your patients' needs. You will also identify comfort problems more quickly and offer appropriate care. The use of **evidence-informed knowledge**—knowledge based on research or clinical expertise—makes you an informed critical thinker.

Critical thinking requires not only cognitive skills, such as interpretation, analysis, inference, evaluation, explanation, and self-regulation, but also a nurse's habit (disposition) to ask questions, to be well informed, to be honest in facing personal biases, and to always be willing to reconsider and think differently about issues. Without these dispositions, sound critical thinking is unlikely to occur (Facione, 1990; Facione & Facione, 1996; Profetto-McGrath, 2003). When applied to nursing, these core critical thinking skills and critical thinking dispositions reveal the complex nature of the **clinical decision-making process** (Table 11-1). Being able to apply all of these skills and acquiring all of these critical thinking habits take time and practice. You also need to have a sound knowledge base and thoughtfully consider the knowledge you gain when caring for patients. Being open-minded, inquisitive, and systematic in thinking about practice situations will also help you incorporate research findings in your clinical decision making (Profetto-McGrath et al., 2003).

Nurses who apply critical thinking in their work consider all aspects of a situation and make well-reasoned judgements about a variety of possible alternative actions rather than hastily and carelessly implementing solutions (Kataoka-Yahiro & Saylor, 1994). For example, nurses who work in crisis situations such as child abuse and suicide prevention programs act quickly when patient problems develop. These nurses must, however, exercise discipline in decision making to avoid premature and inappropriate decisions. Learning to think critically helps you to care for patients as their advocate and to make better informed choices about their care. Critical thinking is more than just problem solving; it is an attempt to continually improve how you apply knowledge when faced with problems in patient care.

A Critical Thinking Model for Clinical Decision Making

Thinking critically is becoming the benchmark or standard for professional nursing competence. To help you in the development of critical thinking, this text offers a model for critical thinking. Because critical thinking in nursing is complex, a model helps explain what is involved as you make clinical decisions and judgements about your patients. Kataoka-Yahiro and Saylor (1994) developed a model of critical thinking for nursing judgement based in part on previous work by Paul (1993), Glaser (1941), Perry (1979), and Miller and Malcolm

► **TABLE 11-1** Critical Thinking Skills and Dispositions

Elements of Decision-Making Process

Skill

Interpretation

Be orderly in data collection. Look for patterns to categorize data (e.g., formulate nursing diagnoses [see Chapter 12]). Clarify any data about which you are uncertain.

Analysis

Be open-minded as you look at information about a patient. Do not make careless assumptions. Ask whether the data reveal what you believe is true or whether other scenarios are possible.

Inference

Examine meanings and relationships in the data. Form reasonable hypotheses and conclusions, on the basis of the patterns observed.

Explanation

Assess all situations objectively. Use criteria (e.g., expected outcomes) to determine the effectiveness of nursing actions. Identify required changes. Reflect on your own behaviour.

Explanation

Support your findings and conclusions. Use knowledge and experience to select the strategies you use in the care of patients.

Self-regulation

Reflect on your experiences. Adhere to standards of practice. Apply ethical principles in your nursing practice. Identify in what way you can improve your own performance.

Dispositions or Habits

Truth seeking

Learn what is actually happening in a situation. Consider scientific principles and evidence, even if they do not support your preconceptions or personal beliefs.

Open-mindedness

Be receptive to new ideas and tolerant of other points of view. Respect the right of other people to hold different opinions. Be aware of your own prejudices.

Analyticity

Determine the significance of a situation. Interpret meaning. Anticipate possible results or consequences. Use evidence-informed knowledge in your nursing practice.

Systematicity

Be organized and focused in data collection. Use an organized approach to problem solving and decision making.

Self-confidence

Trust your own reasoning processes. Seek confirmation from experts when uncertain.

Inquisitiveness

Actively seek new knowledge.

Maturity

Accept that multiple solutions are possible. Reflect on your own judgements; be willing to consider other explanations. Use prudence in making, suspending, or revising judgements.

Adapted from Facione, P. (1990). *Critical thinking: A statement of expert consensus for purposes of educational assessment and instruction. The Delphi report: Research findings and recommendations prepared for the American Philosophical Association* (ERIC Doc No. ED 315-423). Washington, DC: Educational Resources Information Center (ERIC).

(1990) (Figure 11-1). The model defines the outcome of critical thinking: nursing judgement that is relevant to nursing problems in a variety of settings.

Throughout this text, this model is used for applying critical thinking during the **nursing process** (see Chapter 5). Each clinical chapter of the text (Chapters 31 to 48) is organized by the steps of the nursing process and includes both scientific and nursing knowledge. It is your knowledge base (the first critical thinking component) that prepares you to make clinical judgements as a nurse. Figure 11-1 demonstrates how to apply elements of critical thinking in assessing patients, in planning the interventions you provide, and in evaluating your results. Applying each element of this model in the way you think about patients will help you become a confident and effective professional.

Levels of Critical Thinking in Nursing

Your ability to think critically grows as you gain new knowledge and experience in nursing practice. Kataoka-Yahiro and Saylor (1994) developed a critical thinking model that incorporates three levels of critical thinking in nursing: basic, complex, and commitment. As a beginning nursing student, you apply the critical thinking model at the basic level. As you advance in practice, you adopt complex critical thinking and commitment.

Basic Critical Thinking

At the basic level of critical thinking, a learner trusts that experts have the right answers for every problem. Thinking is concrete and based on a set of rules or principles. For example, as a student nurse, you use a hospital's procedure manual to confirm how to insert a Foley catheter. In completing this procedure for the first time, you will probably follow the procedure step by step without adjusting the procedure to meet a patient's unique needs (e.g., positioning to minimize the patient's pain or mobility restrictions) because you do not have enough experience to know how to individualize the procedure. At this level, answers to complex problems are seen to be either right or wrong (e.g., the Foley catheter balloon contains too much or not enough sterile water), and you may believe that one right answer exists for each problem. As you gain more experience in nursing, you will begin to explore the diverse opinions and values of experts (e.g., instructors and staff nurse role models) and engage in more complex critical thinking.

Complex Critical Thinking

When you engage in complex critical thinking, you begin to separate your thinking processes from those of authorities and to analyze and examine choices more independently. Your thinking abilities and initiative to look beyond expert opinion begin to change, as you realize that alternative, and perhaps conflicting, solutions to a problem or issue exist.

Consider the following case study:

Mr. Rosen is a 36-year-old man who injured his back in a skiing accident. He suffers from chronic pain but is refusing to take a prescribed analgesic. While discussing the importance of rehabilitation with Mr. Rosen, the nurse, Edwina, learns that Mr. Rosen practises meditation at home. In complex critical thinking, Edwina recognizes that for pain relief, the patient has options other than accepting analgesics. Edwina decides to also discuss other nonpharmacological interventions with Mr. Rosen and his other health care providers even though not all may agree about their potential efficacy in controlling his pain.

In complex critical thinking, you are willing to consider other options in addition to routine procedures when complex situations develop. As a nurse, you learn to weigh the benefits and risks of each potential solution before making a final decision. Thinking becomes more creative and innovative as you explore a broad range of perspectives and alternative solutions.

Commitment

The third level of critical thinking is commitment. You anticipate the need to make choices without assistance from

Figure 11-1 Critical thinking model for nursing judgement. **Source:** Redrawn from Kataoka-Yahiro, M., & Saylor, C. (1994). A critical thinking model for nursing judgment. *Journal of Nursing Education*, 33(8), 351. Adapted from Glaser, E. (1941). *An experiment in the development of critical thinking*. New York: Bureau of Publications, Teachers College, Columbia University; Miller, M., & Malcolm, N. (1990). Critical thinking in the nursing curriculum. *Nursing & Health Care*, 11, 67; Paul, R. W. (1993). The art of redesigning instruction. In Willsen, J., & Blinker, A. J. A. (Eds.). *Critical thinking: How to prepare students for a rapidly changing world*. Santa Rosa, CA: Foundation for Critical Thinking; and Perry, W. (1979). *Forms of intellectual and ethical development in the college years: A scheme*. New York: Holt, Rinehart, & Winston.

other professionals, and then you assume responsibility and accountability for those choices. As a nurse, you do more than just consider the complex alternative solutions that a problem poses. At the commitment level, you choose an action or belief on the basis of the alternative solutions available, and you stand by your choice. Sometimes an action is to not take action, or you may choose to delay an action until a later time as a result of your experience and knowledge. Because you take accountability for the decision, you give attention to the results of the decision and determine whether it was appropriate.

Components of Critical Thinking in Nursing

Critical thinking consists of five components: knowledge base, experience, competencies, qualities, and standards. These elements explain how nurses make clinical judgements that are necessary for safe, effective nursing care (Box 11-1).

Specific Knowledge Base

To think critically, establish accurate clinical judgements and decisions, and improve clinical practice (Di Vito-Thomas, 2005), nurses must possess a sound knowledge base. Your knowledge base includes information and theory from the basic sciences, humanities, behavioural sciences, and nursing. Nurses use their knowledge base in a different way than other health care providers because they think holistically about patient problems and health-related matters. For example, a nurse's broad knowledge base offers a physical, psychological, social, moral, ethical, and cultural view of patients and their health concerns. The breadth and depth of your knowledge influences your ability to think critically about nursing problems. Consider the scenario on the following page:

► BOX 11-1

Components of Critical Thinking in Nursing

- I. Specific knowledge base
- II. Experience in nursing
- III. Critical thinking competencies
 - A. General critical thinking competencies (scientific method, problem solving, and decision making)
 - B. Specific critical thinking competencies in clinical situations (diagnostic reasoning, clinical inference, and clinical decision making)
 - C. Specific critical thinking competency in nursing (use of nursing process)
- IV. Attitudes for critical thinking
- V. Standards for critical thinking
 - A. Intellectual standards
 - B. Professional standards
 1. Ethical criteria for nursing judgement
 2. Criteria for evaluation
 3. Professional responsibility

The art of redesigning instruction. In Willsen, J., & Blinker, A. J. A. (Eds.). *Critical thinking: How to prepare students for a rapidly changing world*. Santa Rosa, CA: Foundation for Critical Thinking.

Robert Perez previously earned a bachelor's degree in education and taught high school for one year. He has successfully completed the required human and biological science courses in his nursing program as well as those related to health ethics, fundamental nursing concepts, and communication principles. His first clinical course focuses on health promotion, with a clinical assignment in an outpatient primary care clinic. Although he is still new to nursing, his experience as a teacher and his preparation and knowledge base in nursing will help him know how to begin to make clinical decisions about patients' self-care and health promotion practices.

Experience

Nursing is a practice discipline. Clinical nursing experiences are necessary for you to acquire clinical decision-making skills (Roche, 2002). In clinical situations, you learn from observing, sensing, talking with patients and families, and then reflecting actively on your experiences. Clinical experience is the laboratory for evaluating nursing knowledge. You learn that "text-book" approaches form the basis for nursing practice, but you make safe adaptations or revisions in approaches to accommodate the setting, the unique qualities of the patient, and the experience you gained from caring for previous patients. With experience, you begin to understand clinical situations, recognize cues of patients' health patterns, and interpret cues as relevant or irrelevant (Tanner, 2006), and your critical thinking skills advance beyond the basic level. You also learn to seek new knowledge as needed, act quickly when events change, and make quality decisions that promote the patient's well-being. It is important for you to admit to any limitations in your knowledge and skills. Critical thinkers admit what they do not know and try to acquire the knowledge needed to make correct decisions. A patient's safety and welfare are at risk if you do not admit your inability to deal with a practice problem. You must rethink the situation, acquire additional knowledge, and then use new information to form opinions, draw conclusions, and take appropriate action. Perhaps the best lesson to be learned by a new nursing student is to value all patient experiences, which enable you to build new knowledge and inspire innovative thinking.

During the previous summer, Robert worked as a nurse assistant in a long-term care facility. This experience provided him with valuable experience in interacting with older adults and in giving basic nursing care. Specifically, he has been able to develop good interviewing skills and understand the importance of the family in an individual's health. He has also learned that older adults require more time to perform activities such as eating, bathing, and grooming, and so he has adapted skill techniques for dealing with this requirement. His time in the physical assessment laboratory and the time he worked in the nursing home helped him begin to be a careful observer. As he reflects on his experiences, Robert also knows that much of what he learned can be applied in promoting health, wellness, and independence among the older patients who attend the outpatient primary care clinic for routine follow-up visits.

Becoming familiar with practice standards developed by clinical experts assists you in enhancing your knowledge base. For example, the Best Practice Guidelines developed by the Registered Nurses' Association of Ontario (RNAO) include standards for patient-centred nursing care and for a number of clinical conditions, such as asthma, chronic obstructive pulmonary disease, diabetes, and depression. Other standards focus on nursing practice issues such as embracing cultural diversity and fostering collaborative practice. Visit the RNAO's

Web site (<http://www.rnao.org/bestpractices/>), as well as the Web site of the professional nursing association in the province or territory in which you reside, to learn more about the wide range of practice guidelines and to develop a sound knowledge base for your nursing practice. Including a focus on wellness in the care you provide means you also need to think about how the social determinants of health (see Chapter 1) influence patient access to the resources they need in the community to deal with chronic disease, prevent illness and injury, and increase their health and well-being (Canadian Nurses Association, 2009). Incorporating interprofessional collaboration, including shared decision making and working in partnership with other health providers, in your practice as a nurse enhances health outcomes for the individuals, families, and communities you encounter (Canadian Interprofessional Health Collaborative, 2010).

Critical Thinking Competencies

Kataoka-Yahiro and Saylor (1994) described critical thinking competencies as the cognitive processes that a nurse uses to make judgements about the clinical care of patients. They include general critical thinking, specific critical thinking in clinical situations, and specific critical thinking in nursing. General critical thinking competencies are not unique to nursing. They include the scientific method, problem solving, and decision making. Specific critical thinking competencies in clinical situations include diagnostic reasoning, clinical inference, and clinical decision making. The specific critical thinking competency in nursing involves use of the nursing process.

General Critical Thinking Competencies

Scientific Method. The scientific method is a systematic, ordered approach to gathering data and solving problems that is used in nursing, medicine, and various other disciplines. Nurse researchers use the scientific method to verify that a set of facts is true when testing research questions in nursing practice situations. Research incorporating the scientific method contributes to evidence-informed nursing practice and the development of best practice guidelines.

The scientific method has five steps:

- Identification of the problem
- Collection of data
- Formulation of a research question or hypothesis
- Testing of the question or hypothesis
- Evaluation of the results of the test or study

Consider the following example of the scientific method in nursing practice:

A nurse caring for patients who receive large doses of chemotherapy for ovarian cancer detects a pattern whereby these patients develop severe inflammation of the mouth (mucositis) (identifies the problem). The nurse reads research articles (collects data) about mucositis and learns about evidence that cryotherapy, in which patients keep ice in their mouths during the chemotherapy infusion, reduces the severity of the mucositis after treatment. The nurse asks (forms research question), "Can ovarian cancer patients who receive chemotherapy have less severe mucositis when given cryotherapy instead of standard mouth rinse in the oral cavity?" The nurse then designs a study that compares the incidence and severity of mucositis in a group of patients who use cryotherapy with those in patients who use traditional mouth rinse (tests the question). The nurse hopes that the results from the study will give oncology nurses a better approach for reducing the

frequency and severity of mucositis in cancer patients. A nurse in another oncology setting critically analyzes the study before implementing its recommendations for patient care (evaluates the results of the study).

Problem Solving. Everyone faces problems every day. When a problem arises, people obtain information and then use the information, in addition to what they already know, to find a solution. Patients routinely present problems in nursing practice. For example, a home care nurse visits a patient and learns that the patient cannot describe what medications she has taken for the past three days. The nurse must solve the problem of why the patient is not adhering to her medication schedule. The nurse knows the patient was recently discharged from the hospital and five medications were prescribed. When the nurse asks the patient to show the medications that she takes in the morning, the nurse notices that the patient has difficulty reading the medication labels. The patient is able to tell the nurse the names of the medications she is to take but is uncertain about the times of administration. The nurse recommends having the patient's pharmacy relabel the medications in larger lettering. In addition, the nurse shows the patient examples of pill organizers that will help her sort her medications by time of day for a period of seven days.

Effective **problem solving** also involves evaluating the solution over time to be sure that it is still effective. It becomes necessary to try different options if a problem recurs. As a continuation of the example just described, the nurse finds during a follow-up visit that the patient has organized her medications correctly and is able to read the labels without difficulty. The nurse obtained information that correctly clarified the cause of the patient's problem, and the nurse tested a solution that proved successful. Having solved a problem in one situation adds to the nurse's experience in practice and allows the nurse to apply that knowledge in future situations with patients.

Decision Making. When you face a problem or situation and need to choose a course of action from several options, you are making a decision. **Decision making** is a product of critical thinking that focuses on problem resolution. Following a set of criteria helps you make a well-reasoned decision. For example, decision making occurs when a person chooses a fitness consultant. To make a decision, the person has to recognize and define the problem (need for a physical activity) and assess all options (consider recommended trainers or choose one on the basis of proximity to the person's home). The person has to weigh each option against a set of criteria (e.g., credentials, reputation, experience), test possible options (interview potential trainers, assess safety of equipment), consider the consequences of the decision (increased fitness, risk of injury), and then make a final decision. Although the criteria follow a sequence of steps, decision making involves moving back and forth between steps when all criteria are considered. Decision making leads to informed conclusions that are supported by evidence and reason. Examples of decision making include deciding on a choice of dressings for a patient with a surgical wound or selecting the best approach for teaching a family how to assist a patient who is returning home after a stroke. You learn to make sound decisions by approaching each clinical situation thoughtfully and by applying each component of the decision-making process described previously.

Specific Critical Thinking Competencies in Clinical Situations

Diagnostic Reasoning and Inference. As soon as you receive information about a patient in a clinical situation, you begin **diagnostic reasoning**, a process of determining a patient's health status after you make physical and behavioural observations and after you assign meaning to the behaviours, physical signs, and symptoms exhibited by the patient. The information that you collect and analyze leads to a diagnosis of the patient's condition. An expert nurse sees the context of a patient situation (e.g., recognizes that a patient who is feeling lightheaded, has blurred vision, and has a history of diabetes is experiencing a problem with blood glucose levels), observes patterns and themes (e.g., symptoms including weakness, headache, hunger, and visual disturbances that suggest hypoglycemia), and chooses an appropriate intervention quickly (e.g., offers a food source containing glucose) (Ferrario, 2004). Considering the context of the situation enhances the nurse's analytic skills (Ironside, 2005) and results in a more accurate diagnosis.

Part of diagnostic reasoning is **clinical inference**: the process of drawing conclusions from related pieces of evidence (Smith Higuchi & Donald, 2002). An inference involves forming patterns of information from data before making a diagnosis. Seeing that a patient has lost his appetite and experienced a loss of weight over the past month, the nurse infers that the patient has a nutritional problem. An example of diagnostic reasoning is forming a nursing diagnosis such as imbalanced nutrition, less than body requirements (see Chapter 42).

Often you cannot make a precise nursing diagnosis during your first meeting with a patient. You will sometimes sense that a problem or health concern exists, but you do not have sufficient data to make a specific diagnosis. Some patients' physical conditions limit their ability to tell you about symptoms. Other patients may choose not to share sensitive and important information during your initial assessment. Patients' behaviours and physical responses may become observable only under certain conditions not present during your initial assessment. When you are uncertain of a diagnosis, continue data collection, which may include consulting with expert nurses or other health care providers. As a nurse, you must critically analyze changing clinical situations until you are able to determine the patient's unique situation. Diagnostic reasoning is a continuous behaviour in nursing practice.

In diagnostic reasoning, use patient data that you gather to logically explain a clinical judgement. For example, after turning a patient over in bed, you see an area of redness and a small blister on his right hip. You palpate the area and note that it is warm to the touch, and the patient complains of tenderness there. You push on the area with your finger, and, after you release pressure, the area does not blanch or turn white. You think about what you know about normal skin integrity and the effects of pressure. You form the conclusion the patient has a Stage I pressure ulcer. As a new student, confirm your judgement with experienced nurses. At times, your clinical judgement may be incorrect (e.g., a blistered area is indicative of a Stage II pressure ulcer; <http://mao.ca/bpg/fact-sheets/taking-pressure-preventing-pressure-ulcers>); however, nurse experts will give you feedback to build on in future clinical situations.

Nurses do not make medical diagnoses, but they do assess and monitor patients closely and compare the patient's signs and symptoms with those that are common to a medical

diagnosis. This type of diagnostic reasoning helps nurses and other health care providers pinpoint the nature of a problem more quickly and select proper interventions. Similarities and differences between medical and nursing diagnoses are described in more detail in Chapter 12.

Clinical Decision Making. Clinical decision making is a problem-solving activity that focuses on defining patient problems and selecting appropriate treatments (Smith Higuchi & Donald, 2002). Nurses are responsible for making accurate and appropriate clinical decisions. Clinical decision making distinguishes professional nurses from technical personnel. It is the professional nurse, for example, who takes immediate action when a patient's clinical condition deteriorates, decides whether a patient is experiencing complications that call for notification of a physician, or decides whether a teaching plan for a patient is ineffective and necessitates revision. Benner (1984) described clinical decision making as judgement that includes critical and reflective thinking and action and the application of scientific and practical knowledge.

Clinical judgement requires that you recognize the salient aspects of a clinical situation, interpret their meanings, and respond appropriately. It includes four components: noticing or grasping the situation; interpreting or developing a sufficient understanding of the situation to respond; responding or deciding on a course of action; and reflecting on or reviewing the actions taken and their outcomes. In making a clinical judgement, you consider the context of the situation and rely on analytic processes, intuition, and narrative thinking (i.e., thinking that occurs as a result of telling and interpreting stories). As you reflect on actions taken, you acquire clinical learning, which contributes to future clinical judgements (Tanner, 2006).

Nurses regularly encounter practice situations in which little is straightforward (Hartrick Doane & Brown, 2011). Each patient's problems are unique and products of many factors, including the patient's physical health, lifestyle, culture, relationship with family and friends, living environment, and experiences. As a nurse, you do not always have a clear picture of the patient's needs and the appropriate actions to take when you first meet a patient. Instead, you must learn to question and explore different perspectives and interpretations in order to find a solution that benefits the patient (Box 11-2).

When you approach a clinical problem, such as a patient who is experiencing difficulty walking, you make a decision that identifies the problem (e.g., right-sided weakness) and choose nursing interventions (e.g., teaching the use of appropriate assistive devices) for that patient. Nurses constantly make clinical decisions to improve a patient's health or maintain wellness. Clinical decision making requires careful reasoning so that you choose the options for the best patient outcomes on the basis of the patient's condition and the priority of the problem or health concern.

You improve your clinical decision making by knowing your patients. Nurse researchers found that expert nurses develop a level of knowing that leads to pattern recognition of patient's symptoms and responses (White, 2003). For example, an expert nurse who has worked on a general surgery unit for many years is more likely to detect signs of internal hemorrhage (e.g., fall in blood pressure, rapid pulse, change in consciousness) than is a new nurse. Over time, a combination of knowledge, experience, time spent in a specific clinical area, and the quality of relationships formed with patients allow expert nurses to know clinical situations and quickly anticipate

* BOX 11-2 RESEARCH HIGHLIGHT

Working Relationships of Public Health Nurses and High-Priority Families

Focus

In this study, the nature of working relationships of public health nurses and high-risk (i.e., high-priority) families in northern communities in Canada was examined with the intent of informing nursing practice, education, and policy.

Abstract

The researchers conducted interviews with 32 families, 25 public health nurses, and 3 lay visitors. An interpretive hermeneutic approach was used to examine the practices and problems nurses and families encountered as care was being provided to a vulnerable, isolated, and often marginalized population, while navigating the complexity and unpredictability of working and living in the same small community. The working relationships of public health nurses and high-risk families were found to be multifaceted and to involve processes related to engaging and entering into relationships, maintaining relationships, and negotiating roles and boundaries.

Evidence-Informed Practice

The relationships of public health nurses and high-risk families extend beyond the home, clinic, or office and intersect with other facets of everyday life within the community. This means that public health nurses must be attuned to having and using power, maintaining privacy and confidentiality, and setting and crossing boundaries in their work with high-risk families. Working with high-risk families also means that public health nurses must engage them in a manner that opens possibilities for understanding, encourages reflection, builds on the strengths of the families, and invites healing.

Reference: Moules, N. J., MacLeod, M. L. P., Thirsk, L. M., & Hanlon, N. (2010). "And then you'll see her in the grocery store": The working relationships of public health nurses and high-priority families in northern Canadian communities. *Journal of Pediatric Nursing*, 25, 327–334.

and select the right course of action (Tanner et al., 1993). Spending more time during initial patient assessments to both observe patient behaviour and measure physical findings is a way to improve knowing your patients. Also, consistently monitoring patients as problems occur helps you see how clinical changes develop over time. The selection of nursing actions is built on both clinical knowledge and patient data, including the following:

- The identified status and situation of the patient
- Knowledge about the clinical variables (e.g., patient's age, seriousness of the problem, pathological process of the problem, patient's pre-existing disease conditions) involved in the situation and how the variables are linked together
- Knowledge about the usual patterns of any diagnosed problem or prognosis and a judgement about the likely course of events and outcomes of the diagnosed problem, in view of any co-existing health risks the patient also possesses
- Any additional relevant information about the patient's daily living situation, functional capacity, and social resources
- Knowledge about the nursing interventions available and the way in which specific actions will predictably affect the patient's situation

After determining a patient's nursing care priorities, you select actions most likely to relieve each problem or to promote health, wellness, and quality of life. A wide range of choices is often available, from nurse-administered to patient self-care strategies. You collaborate with the patient and then select, test, and evaluate the chosen approaches. Making an accurate clinical decision allows you to set priorities for nursing action. Because each situation involves different patients and different variables, a certain activity is sometimes more of a priority in one situation and less of a priority in another. For example, if a home care patient is physically dependent, unable to eat, and incontinent of urine, skin integrity is of higher priority than if the patient were immobile but continent of urine and able to eat a normal diet. Do not assume that certain health situations produce automatic priorities. For example, an adolescent who has embarked on a smoking cessation program is expected to experience some withdrawal symptoms, which often become a priority of care. However, if the patient is experiencing anxiety about potential weight gain that decreases her ability to participate fully in the program, it becomes necessary for you to focus on ways to relieve the anxiety before the smoking cessation measures will be effective.

Nurses make decisions about individual patients and about groups of patients. You use criteria such as the clinical condition of the patients, Maslow's hierarchy of needs, risks involved in treatment delays, and patients' expectations of care to determine which patients have the most urgent priorities for care. For example, a patient in a community care centre who is experiencing a sudden drop in blood pressure along with a change in consciousness requires your attention immediately, as opposed to a small child who requires a routine immunization or a group of expectant parents attending a prenatal class. In order for you to manage the wide variety of problems associated with groups of patients, skillful, prioritized decision making is crucial (Box 11-3).

Nursing Process as a Critical Thinking Competency

Nurses apply the nursing process as a critical thinking competency when delivering patient care. The nursing process is a five-step clinical decision-making approach that consists of assessment, diagnosis, planning, implementation, and evaluation (see Chapters 12 to 14). The purpose of the nursing process

is to assist nurses in identifying and treating patients' health-related concerns and to help patients meet agreed-upon outcomes for better health (Figure 11-2). The nursing process incorporates general (e.g., scientific method, problem solving, and decision making) and specific critical thinking competencies (e.g., diagnostic reasoning, inference, and clinical decision making), described earlier in this chapter, in a manner that focuses on a particular patient's unique needs. The format of the nursing process is unique to the discipline of nursing and provides a common language and process for nurses to "think through" patients' clinical problems (Kataoka-Yahiro & Saylor, 1994). Chapter 12 describes the nursing process in more detail.

The nursing process is often called a blueprint or plan for care. It allows flexibility for use in all clinical settings. When you use the nursing process, you identify a patient's health-related concerns, clearly define a nursing diagnosis or collaborative problem, determine priorities of care, and set goals and expected outcomes of care. Then you develop and communicate a plan of care, perform nursing interventions, and evaluate the effects of your care. Involving your patient in each step of the nursing process helps ensure that care is patient centred. When you become more competent in using the nursing process, you are able to focus on multiple problems or diagnoses and to move back and forth between steps when considering all the information available to you about a patient's concerns.

Attitudes for Critical Thinking

The fourth component of the critical thinking model incorporates the attitudes needed to think critically. An important part of critical thinking is interpreting, evaluating, and making judgements about the adequacy of various arguments and available data. Attitudes determine how a successful critical thinker approaches a problem or a situation that necessitates decision making. For example, when a patient complains of anxiety before undergoing a diagnostic procedure, the curious nurse explores possible reasons for the patient's concerns. The nurse also exhibits discipline and perseverance in taking responsibility to complete a thorough assessment to find the sources of the patient's anxiety. Engaging in inquiry involves an ability to recognize that problems exist and that you need evidence in support of what you suppose to be true (Watson

► BOX 11-3

Clinical Decision Making for Groups of Patients

- Identify the nursing diagnosis and collaborative problems of each patient.
- Analyze patients' diagnoses or problems and decide which are most urgent in light of the patient's basic needs, changing or unstable status, and problem complexity.
- Consider the resources available for managing each problem, including unregulated care providers assigned to work with you and the patients' family members.
- Consider how to involve the patients as decision makers and participants in care.
- Decide how to combine activities to resolve more than one patient problem at a time.
- Decide what, if any, nursing care procedures to delegate to unregulated care providers so that you are able to spend your time on activities requiring professional nursing knowledge.

Figure 11-2 Five-step nursing process model.

& Glaser, 1980). Knowing when you need more information, knowing when information is misleading, and recognizing your own knowledge limits and personal biases are examples of how critical thinking attitudes play a key role in decision making.

Standards for Critical Thinking

The fifth component of the critical thinking model includes intellectual and professional standards (Kataoka-Yahiro & Saylor, 1994).

Intellectual Standards. An intellectual standard is a guideline or principle for rational thought. You apply such standards when you conduct the nursing process. When you consider a patient problem, apply intellectual standards such as thoroughness, precision, accuracy and consistency to make sure that all clinical decisions are sound. Efficacious use of the intellectual standards in clinical practice ensures that you do not perform critical thinking haphazardly.

Professional Standards. Professional standards for critical thinking refer to ethical criteria for nursing judgements, evidence-informed criteria for evaluation, and criteria for professional responsibility. Professional standards promote the highest level of quality nursing care for individuals and groups in institutional and community-based settings.

Ethical Criteria for Nursing Judgement. Patient care requires more than just the memorization and application of scientific knowledge (Ironside, 2005). Effective nursing practice reflects sound ethical principles. Being able to focus on a patient's values and beliefs helps you make clinical decisions that are just, faithful to the patient's choices, and beneficial to the patient's health and well-being. *The Code of Ethics for Registered Nurses* (Canadian Nurses Association, 2008) is based on core values that serve as a guide to ethical decision making in nursing practice. Among these values and ethical responsibilities are providing safe, compassionate, competent, and ethical care; promoting health and well-being; promoting and respecting informed decision making; preserving dignity; maintaining privacy and confidentiality; promoting justice; and being accountable. Critical thinkers maintain a sense of self-awareness through conscious awareness of their own values, beliefs, and feelings and of the multiple perspectives of patients, family members, staff, and peers in clinical situations. Chapter 7 summarizes ethical standards to use when you are faced with ethical dilemmas or problems.

One of the patients in a community health clinic is a young man who has signs and symptoms of chlamydia, a sexually transmitted infection. The patient has had the symptoms for more than three weeks and voices concern about what it will mean to have the infection. Richard, a nurse, examines the young man and finds that the patient has redness and itching on his penis, with a yellowish discharge. Richard checks further and asks whether the patient has pain on urination. He also assesses the patient for fever. Richard has limited knowledge about chlamydia, and so he consults with the clinic nurse practitioner, who explains the nature of the infection, the risks it poses to the patient, the usual course of treatment, and some of the legal and ethical guidelines that govern nurses' actions when working with patients with sexually transmitted infections. Richard returns to the patient and speaks confidently with him about chlamydia, the reason for his symptoms, the need to tell sex partners about the infection, and the importance of wearing a condom.

Criteria for Evaluation. Nurses routinely use evidence-informed criteria to assess patients' conditions and to

determine the efficacy of nursing interventions. For example, accurate assessment of symptoms such as pain or shortness of breath requires use of assessment criteria such as the duration, severity, location, aggravating or relieving factors, and effects on daily lifestyle (see Chapter 41). In this case, assessment criteria allow you to accurately determine the nature of a patient's symptoms, select appropriate interventions, and later evaluate whether the interventions are effective. Another example is the determination of the stage of a pressure ulcer on the basis of scientific criteria, including temperature, tissue consistency, and depth of the wound (see Chapter 46). The criteria allow you to identify the stage of a pressure ulcer and to track how quickly it heals.

Professional Responsibility. The standards of professional responsibility that a nurse strives to achieve are the standards cited in institutional practice guidelines, professional organizations' standards of practice, and legislation governing nursing practice. To view the nursing practice standards that govern nurses' actions in your jurisdiction, visit the Web site of the professional nursing association in the province or territory in which you reside. These standards outline the responsibilities and accountabilities that a nurse assumes in guaranteeing high-quality health care to the public.

Developing Critical Thinking Skills

To develop critical thinking skills, it is important to learn how to connect knowledge and theory in practice (Box 11-4). Making sense of what you learn in the classroom, from reading, or from dialogue with other students, and then applying it during patient care is always challenging. Learning approaches such as reflective journal writing and concept mapping will assist you in developing and improving your critical thinking skills.

Reflective Journal Writing

How often do you think back on a situation to consider why it occurred? How did you act? What could you have done differently? What knowledge could you have used? **Reflection** is the process of purposefully thinking back or recalling a situation to discover its purpose or meaning. Reflection is necessary for self-evaluation and improvement of nursing practice.

Reflective journal writing is a tool for developing critical thought and reflection through clarifying concepts (Bilinski, 2002). Reflective writing gives you the opportunity to define and express a clinical experience in your own words (Di Vito-Thomas, 2005) and improves your observation and descriptive skills. By keeping a reflective journal of each of your clinical experiences, you are able to explore your perceptions and understanding of the experience and develop the ability to apply theory in practice. Reflective writing invites you to consider questions such as "What have I learned from this experience?" "How will I use what I have learned if I encounter a similar situation in the future?"

Keeping a journal of your patient care experiences will help you become aware of how you use clinical decision-making skills (Kessler & Lund, 2004). Begin by recording notes after a clinical experience. Telling a story and drawing a picture are two additional ways to identify the experience you wish to reflect on. Describe in detail what you felt, thought, and did. Analyze your experience by considering thoughts, feelings, and possible meanings for you and the patient. Challenge any preconceived ideas you have when you look at actual clinical situations. Describe the significance of the experience. Refer to

Decision Making by Baccalaureate Nursing Students

Focus

Researchers agree that decision making is a skill that needs to be taught in nursing education programs but few have examined the kinds of decisions students make in clinical settings and the factors that influence their decision making.

Abstract

In this study, nurse decision making was defined as “a cognitive process requiring patient assessment and problem identification, the identification and consideration of alternatives, the consideration of preferences and values (of all parties involved), the selection of interventions, and the determination of how best to achieve those interventions” (p. 346). Nineteen full-time students in all four levels of a nursing program at a Canadian university completed two reflective journal entries about their decision making in a recent clinical encounter, prior to engaging in a related interview. Key curriculum documents, including program and level goals, and course objectives for the clinical courses in all four levels of the program, were also examined to provide context and help explain student decision making. The study revealed that students made decisions related to encounters with patients, nursing staff, and clinical instructors.

Evidence-Informed Practice

Students at all levels of the program described five key kinds of decisions:

- **Assessment**, including deciding what patient data to gather and how to gather it
- **Intervention**, including deciding what needs to be done to maintain or improve a patient's health
- **Resource**, including deciding who or what the student needs to support them in the decision-making process and how to effectively use the resource
- **Communication**, including deciding who to approach, what communication strategies to use with the patient, nursing staff, or preceptor, and how to communicate with others to engage them in the decision-making process
- **Action**, including deciding whether to proceed with the decision-making process, whether an intervention will be implemented, and whether information will be communicated to another health care provider.

Understanding the kinds of decisions students make is important in developing curricula to enhance students' cognitive abilities and to prepare them to make sound, autonomous decisions when they enter the workplace as graduate nurses.

Reference: Baxter, P. E., & Boblin, S. (2008). Decision making by baccalaureate nursing students in the clinical setting. *Journal of Nursing Education*, 47, 345–350.

your journal often when you care for patients in similar circumstances. Reflecting on your experiences is an important component of monitoring your competence in nursing practice. It also promotes knowledge transfer by enabling you to identify how previously acquired knowledge can be applied in a current or future situation (Nielsen et al., 2007).

Reflective journal writing can also help you learn to “see the other” when working with patients and families, even though you may not have had similar experiences. Instead becoming

a source of fear, diversity and difference can become an opportunity for you to engage in dialogue and come to understand their experience. Reflection allows you to examine your assumptions about what it means to be of a different age, race, or sexual orientation or to suffer from a mental illness. As you enter into the world of the other and begin to appreciate their experience, the degree of difference and potential for alienation are decreased (Binding et al., 2010). “Seeing the other” helps you determine the kinds of interventions that will be most effective in addressing the patient's desired health outcomes.

Concept Mapping

As a nurse, you care for patients who have multiple nursing diagnoses or collaborative problems. A **concept map** is a visual representation of patient problems and interventions that depicts their relationships to one another (Schuster, 2003). The primary purpose of concept mapping is to synthesize relevant data about a patient, including assessment data, nursing diagnoses, health needs, nursing interventions, and evaluation measures (Hill, 2006). Through drawing a concept map, you learn to move beyond memorizing and recalling facts to organizing or linking information in a unique way so that the diverse information you have about a patient begins to connect to form meaningful patterns and concepts. When you see the relationship between the various patient diagnoses and the data that support them, you gain a holistic understanding of a patient's clinical situation. Over time, your concept maps will become more detailed, integrated, and comprehensive as you learn more about the care of a patient and as you care for similar patients (Ferrario, 2004). You will see similarities and differences between patients, which helps you hone your decision-making skills.

Concept maps take many visual forms. Several examples of concept maps are included in other chapters of this textbook. Additional resources are also found in the Web site list at the end of this chapter. Most students follow a model that makes the concept map a working document. As a student, you develop the map during your care for the patient. You begin by obtaining patient data from a variety of sources (e.g., the medical record, pertinent nursing literature, the patient's history and physical examination, and other health care providers). The patient's major medical diagnosis and any comorbid conditions (unrelated medical conditions) usually form the centre of the map. From there, you group patterns of assessment data along the edges of the map. As you identify the different nursing diagnoses, you draw dotted lines to connect the diagnoses that are related.

The links must be accurate in order to show true clinical relationships. On the map, you also list the nursing interventions chosen for the patient. Once again, you see how any one intervention applies to more than one nursing diagnosis. While caring for a patient, you write down the patient's responses to your interventions and any clinical impressions you may have.

The final map gives you a broader and more complex understanding of your patient's health care needs. Save the concept maps you create and use them as a reference as you care for other patients with similar health concerns.

Critical Thinking Synthesis

Critical thinking is a reasoning process by which you use knowledge, reflect on previous experience, and integrate

Figure 11-3 Synthesis of critical thinking with the nursing process competency.

professional practice standards to provide competent and ethical nursing care to patients (Figure 11-3). Thinking critically requires dedication and a desire to grow intellectually. For novice nurses, it is important to learn the steps of the nursing process and to incorporate the elements of the critical thinking model in your practice. The two processes are intertwined in making quality decisions about patient care. The key components of critical thinking are integrated into other chapters in this text to help you better understand its relationship to the nursing process and to making quality judgements and decisions about patient care.

❖ KEY CONCEPTS

- Critical thinking is a process acquired through learning and experience.
- Nurses who apply critical thinking in their work focus on options for solving problems and making decisions, rather than rapidly and carelessly adopting solutions.
- Following a procedure step by step without adjusting to a patient's unique needs is an example of basic critical thinking.
- In complex critical thinking, a nurse learns that alternative and perhaps conflicting solutions to problems exist.
- The critical thinking model combines a nurse's knowledge base, experience, competence in nursing process, qualities, and standards to explain how nurses make clinical judgements that are necessary for safe, effective nursing care.
- In diagnostic reasoning, you collect patient data and then logically develop a clinical judgement, such as a nursing diagnosis.
- When you face a clinical problem or situation and choose a course of action from several options, you are making a clinical decision.
- Clinical learning experiences are necessary for you to acquire clinical decision-making skills.
- You improve your clinical decision making by knowing your patients.
- Clinical decision making involves judgement that includes critical and reflective thinking and action and the application of scientific and practical knowledge.
- The nursing process is a blueprint for patient care that involves both general and specific critical thinking competencies in a way that focuses on the patient's unique needs.
- Critical thinking qualities help a nurse to know when more information is needed, to know when information is misleading, and to recognize personal knowledge limits.
- The use of intellectual standards during assessment ensures a complete database of information.
- Professional standards for critical thinking refer to ethical criteria for nursing judgements, scientific and practice criteria to be used for evaluation, and criteria for professional responsibility.
- Reflective journal writing gives you the opportunity to define and express clinical experiences in your own words.

- Drawing a concept map enables you to gain a broader and more complex understanding of your patient's complex health care needs.

❖ CRITICAL THINKING EXERCISES

1. You are meeting with an obese patient for the first time. She states that she has been successful in losing weight on several occasions but is frustrated by her inability to maintain her weight loss. She reports having tried "virtually every fad diet" and "multiple exercise programs." She admits that as her weight increases, she tends to be become less active. She has become increasingly reluctant to leave her home because of the negative reactions of other people. In listening to her story, you attempt to imagine what it would be like to be in her situation and to examine your biases and assumptions about people who are obese. Your goal is to begin to discuss potential options with her for dealing with her situation. Describe the level of critical thinking that is necessary in this scenario. How will your actions potentially assist in helping this patient develop an effective plan of action?
2. Mr. Yousif is a terminally ill patient receiving home care. His wife and son are asking you about his pain control. Mrs. Yousif is requesting that her husband's medication be increased, even if it means he will not be responsive. She does not want her husband to suffer. The son is vehemently opposed to too much narcotic and feels that his father is still able to make decisions for himself. Mr. Yousif remains alert much of the time and is able to talk with you about his feelings regarding death and his desire to die at home. He seems to appreciate your availability in talking with him. How might you use critical thinking to help the family resolve this complex problem?
3. Construct a concept map that illustrates your definition of professional nursing practice. What are the key components (i.e., assumptions, beliefs, values) of your definition? How are they related (i.e., linked) to each other? How has your definition of professional nursing practice changed since you first entered your nursing program? What factors contributed to this change? Try to incorporate these factors into your concept map.
3. A patient had hip surgery 24 hours ago. The nurse refers to the written plan of care, noting that the patient has a device collecting wound drainage. The physician is to be notified when the accumulation in the device exceeds 100 mL for the day. When the nurse enters the room, the nurse looks at the device and carefully notes the amount of drainage currently in the device. This is an example of
 1. Planning
 2. Evaluation
 3. Intervention
 4. Nursing diagnosis
4. The nurse asks a patient how she feels about her impending surgery for breast cancer. Before the discussion, the nurse reviewed the description in his textbook of loss and grief in addition to therapeutic communication principles. The critical thinking component involved in the nurse's review of the literature is
 1. Experience
 2. Problem solving
 3. Knowledge application
 4. Clinical decision making
5. As the nurse enters a patient's room, she observes that the intravenous line is not infusing at the ordered rate. The nurse checks the flow regulator on the tubing, looks to see whether the patient is lying on the tubing, checks the connection between the tubing and the intravenous catheter, and then checks the condition of the site where the intravenous catheter enters the patient's skin. She readjusts the flow rate, and the infusion begins at the correct rate. This is an example of
 1. Inference
 2. Reflection
 3. Problem solving
 4. Evidence-informed decision making
6. The nurse sits down to talk with her patient, who lost her sister two weeks ago. The patient reports that she is unable to sleep, feels very fatigued during the day, and is having trouble at work. The nurse asks her clarify the type of trouble, and the patient explains that she cannot concentrate or even solve simple problems. The nurse records the results of her assessment, describing the patient's problem as ineffective coping. This conclusion reflects the nurse's use of
 1. Inference
 2. Diagnostic reasoning
 3. Best practice guidelines
 4. Professional practice standards

❖ REVIEW QUESTIONS

1. You are teaching a 12-year-old boy how to self-administer insulin. After discussing the techniques and demonstrating an injection, you ask him to try it. After two attempts, it is obvious that he does not understand how to prepare the correct dose. You review your approach with the patient carefully and ask a colleague for her suggestions about how to improve your teaching skills. This is an example of
 1. Reflection
 2. Risk taking
 3. Patient assessment
 4. Care plan evaluation
2. A nurse uses an institution's procedure manual to confirm how to change a patient's nasogastric tubing. The level of critical thinking the nurse is using is
 1. Commitment
 2. Scientific method
 3. Basic critical thinking
 4. Complex critical thinking
7. In observing a new mother breastfeeding her baby, the public health nurse observes that the baby is fussy and is not sucking effectively. The nurse reviews the baby's record and finds that he has lost a considerable amount of weight since birth. The nurse conducts an assessment and notes that the baby has poor skin turgor. The mother reports that he urinates infrequently and sleeps only for very short periods of time between feedings. The nurse concludes that the baby is dehydrated and is at risk of becoming malnourished. This is an example of
 1. Inference
 2. Problem solving
 3. Diagnostic reasoning
 4. Applying nursing practice standards

✦ RECOMMENDED WEB SITES

Canadian Nurses Association: <http://www.cna-nurses.ca>

A wide range of valuable resources, including the *Code of Ethics for Registered Nurses* (CNA, 2008), can be found on the Web site of the Canadian Nurses Association. This Web site also links to the Web sites of each of the provincial and territorial professional nursing associations in Canada. Visit these Web sites and become familiar with the kinds of resources that are available to you. The position papers and other documents found on these Web sites demonstrate how Canadian nurse leaders have used critical thinking to explore important issues in nursing and nursing practice.

IHMC CMap Tools: A Modelling Kit: <http://cmap.ihmc.us>

This Web site not only provides an example of a concept map but also provides instruction about how to create one. It illustrates components of a concept map and their relationship to each other. Searching the Internet using the terms "concept maps" and "nursing" will provide numerous other examples.

Insight Assessment/California Academic Press: <http://www.insightassessment.com/articles.html>

A wide array of articles and case studies related to critical thinking, tools to measure your critical thinking skills, and other valuable resources can be found on this Web site. Many of these resources can be downloaded for free; others are available for purchase.

The Critical Thinking Community: <http://www.criticalthinking.org>

The section of this Web site titled "The Thinker's Guide Series" includes links to a number of short booklets that explore subjects such as critical thinking concepts and tools; improving your reading, writing, and study skills; and ethical reasoning.

Critical Thinking on the Web: A Directory of Quality Online Resources: <http://www.austhink.org/critical/index.htm>

This Web site links to a wide range of articles in which critical thinking is examined from a variety of perspectives, including nursing. It also contains links to a variety of tutorials that you can use to improve your critical thinking skills.

Critical Thinking Strategies: Concept Mapping: http://cord.org/txcollabnursing/onsite_conceptmap.htm

This Web site provides examples of the use of concept maps in nursing practice.

Student Resources: Critical Thinking Skills: <http://distance.uvic.ca/students/thinking.htm>

This online tutorial assists students in exploring the importance of critical thinking in reading, writing, reasoning, and making judgements.

Nursing Assessment and Diagnosis

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by S. Helen Fraser, RN, MN, Debbie A. Brennick, RN, MN, and Willena I. Nemeth, RN, MN

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss the steps of nursing assessment.
- Explain the relationship of critical thinking to assessment.
- Differentiate between subjective and objective data.
- Discuss the purposes of a client interview.
- Discuss how the use of interview techniques helps clients describe their health histories.
- Describe the components of a nursing history.
- Describe the relationship between data collection and data analysis.
- Explain the relationship between data interpretation, validation, and clustering.
- Conduct a nursing assessment.
- Differentiate between a nursing diagnosis, medical diagnosis, and collaborative problem.
- Discuss the relationship of critical thinking to the nursing diagnostic process.
- Describe the steps of the nursing diagnostic process.
- Develop a concept map.
- Explain how defining characteristics and the etiological process individualize a nursing diagnosis.
- Explain the benefit of using the NANDA International nursing diagnoses in practice.
- Describe sources of diagnostic errors.
- Identify nursing diagnoses from a nursing assessment.

The nursing process is a problem-solving approach to identifying, diagnosing, and treating the health issues of clients. It is fundamental to how nurses practice. As a nursing student, you will learn the five steps of the nursing process—assessment, diagnosis, planning, implementation, and evaluation—as if they were a linear process. However, the steps are interrelated and overlapping (Chabeli, 2007) (Figure 12-1). The nursing process is considered to be a more dynamic, interactive process; in the clinical setting, practitioners move back and forth within the steps (Jarvis et al., 2009).

Figure 12-1 Five-step nursing process. **Source:** Lewis, S. L., Heitkemper, M. M., Dirksen, S. R., O'Brien, P. G., Barry, M. A., Goldsworthy, S., & Goodridge, D. (2010). *Medical-surgical nursing in Canada: Assessment and management of clinical problems* (2nd ed., p. 9, Fig. 4-1). Toronto: Elsevier Canada.

Consider the following scenario:

Following shift report, Lisa, a registered nurse on an orthopedic nursing unit, enters Ms. Devine's room. Ms. Devine is a 52-year-old woman who sustained an injury, a ruptured lumbar disc, in a fall two months ago. She is scheduled for a lumbar laminectomy this afternoon. When Lisa first observes Ms. Devine, she notes the client is moving in bed awkwardly and is grimacing when she turns. Ms. Devine looks up and states, "Oh, I am so glad you are here. [Sighs] The pain in my back seems worse, and I cannot get comfortable. I cannot sit at all, so I will stay in bed for now. I just dread having this surgery, I will be so glad when this is all over [looks away and avoids eye contact]." Lisa observes Ms. Devine's facial grimace and notes her sighing. She responds, "Ms. Devine, you obviously look uncomfortable and a bit upset. Let me ask you a few questions. Show me where the pain is. On a scale of 0 to 10, with 10 the worst pain ever and 0 no pain, how would you rate your pain? Does it become worse when you turn?" As Ms. Devine responds to the questions, Lisa analyzes the data and considers other relevant information, such as the client's medical diagnosis (ruptured lumbar disc) and knowledge of the alterations that the condition typically causes (e.g., sciatic pain and change in sensation of the lower extremities). Lisa decides that Ms. Devine has acute pain related to pressure on the spinal nerves. Lisa explains to Ms. Devine a plan to help relieve the discomfort. She then administers an ordered analgesic, repositions Ms. Devine, and discusses how Ms. Devine can practise relaxation exercises. Forty minutes later, Lisa returns to Ms. Devine's room to determine whether the pain is relieved and whether she wants to try the relaxation exercises.

Lisa applied the nursing process while caring for Ms. Devine. Each time you meet a client, you will apply the nursing process to provide appropriate and effective nursing care. The

process begins with the first step, **assessment**, the gathering and analysis of information about the client's health status. In the next step, **diagnosis**, you then make clinical judgements about the client's response to health problems in the form of nursing diagnoses. Once you establish appropriate nursing diagnoses, you create a plan of care. **Planning** includes interventions individualized to each of the client's nursing diagnoses. The next step, **implementation**, involves the actual performance of planned interventions. After administering interventions, you conduct an **evaluation** of the client's response and whether the interventions were effective. The nursing process is central to your ability to provide timely and appropriate care to your clients.

The nursing process is a variation of scientific reasoning that allows you to organize and systematize nursing practice. You learn to make inferences about the meaning of a client's response to a health problem or generalize about the patient's functional state of health. A pattern begins to form. For example, if Ms. Devine is having acute back pain, the data allow Lisa to infer that the client's mobility is limited. Lisa gathers more information (e.g., noting how the client moves and whether the client is able to walk, stand, and sit normally) until the client's problem is classified accurately: for example, as the nursing diagnosis *impaired physical mobility related to acute back pain*. The clear definition of the client's problems provides the basis for planning and implementing nursing interventions and evaluating the outcomes of care.

Critical Thinking Approach to Assessment

Assessment is the deliberate and systematic collection of data to determine a client's current and past health status and functional status and to determine the client's present and past coping patterns (Carpenito-Moyet, 2008). Nursing assessment consists of two steps:

- Collection and verification of data from a primary source (the client) and secondary sources (e.g., family, health providers, and client record)
- The analysis of all data as a basis for developing nursing diagnoses, identifying collaborative problems, and developing a plan of individualized care

The purpose of assessment is to establish a **database** about the client's perceived needs, health problems, and responses to these problems. In addition, the data reveal related experiences, health practices, goals, values, and expectations about the health care system.

When a plumber comes to your home to repair a problem you describe as a "leaking faucet," the plumber checks the faucet, its attachments to the water line, and the water pressure in the system to determine the actual malfunction. Similarly, you see clients who will present an initial health problem to you. You then proceed to observe each client's behaviour, ask questions about the nature of the problem, listen to the cues the client provides, and conduct a physical examination (see Chapter 31). Sometimes you also interview family members who are familiar with the client's health problem, and you review any existing medical record data. All of the data you collect form different sets or patterns of information that point to a diagnostic conclusion. Once a plumber knows the source of the faucet leak, he or she is able to repair the faucet. Similarly, once you know the nature and source of a client's health problems, you are able to provide interventions that will restore, maintain, or improve the client's health.

Figure 12-2 Critical thinking and the assessment process.

Critical thinking is important to good assessment (see Chapter 11). Critical thinking allows you to see the big picture when you form conclusions or make decisions about a client's health condition. While gathering data about a client, you synthesize relevant knowledge, recall prior clinical experiences, apply critical thinking **standards** and available evidence, and use standards of practice to direct your assessment in a meaningful and purposeful way (Figure 12-2). Your knowledge of the physical, biological, and social sciences enables you to ask relevant questions and collect history and physical assessment data relevant to the client's presenting health care needs. For example, by knowing that a client has a history of a ruptured lumbar disc, you know to ask whether the client has sciatic pain (characteristic pain that radiates or spreads from the buttocks down the leg) and to question how the discomfort affects the client's ability to walk or sit, inasmuch as these are common symptoms of disc disease. By using good communication skills and critical thinking intellectual standards, you can collect complete, accurate, and relevant data.

Prior clinical experience contributes to the skills of assessment. For example, if you have cared for a client with back pain, you know the pain is sometimes disabling and limits the client's normal motion. Thus, you thoroughly assess the extent to which the pain affects the current client's ability to walk normally and to perform daily living activities. By validating abnormal assessment findings and personally observing assessments performed by skilled professionals, you become competent in assessment. You also learn to apply standards of practice and accepted standards of "normal" for physical assessment data when assessing clients. Use of critical thinking qualities such as creativity, perseverance, and confidence ensure that you compile a comprehensive database.

Data Collection

As you begin a client assessment, think critically about what to assess. On the basis of your clinical knowledge and experience and your client's health history and responses, determine what questions or measurements are appropriate. When you first meet a client, make a quick observational overview or screening. Usually an overview is based on a treatment situation. For example, a community health nurse assesses the neighbourhood and the community of the client; an emergency room nurse uses the circulation-airway-breathing (CAB) sequence; and an oncology nurse focuses on the client's symptoms from disease and from treatment and grief response (Heart and Stroke Foundation of Canada, 2010). In the case of Ms. Devine, Lisa first focuses on the nature and severity of her client's pain, the risk of limited mobility, and the extent of the client's anxiety. She will later expand her assessment to determine whether Ms. Devine has been psychologically prepared for her upcoming surgery.

You learn to differentiate important data from the total data collected. A **cue** is information that you obtain through use of the senses. An **inference** is your judgement or interpretation of those cues. For example, a client's crying is a cue that possibly implies fear or sadness. You ask the client about any concerns and make known any nonverbal expressions you notice in an effort to direct the client to share his or her feelings. It is possible to miss important cues when you conduct an initial overview. However, using creativity, flexibility, inquisitiveness, intuition, and open-mindedness can help you become aware of unusual or unexpected cues (Lunney, 2009). Always try to interpret cues from the client to know how in-depth to make your assessment. Assessment is dynamic and allows you

to freely explore relevant client problems as you discover them.

Begin your assessment by documenting a comprehensive **nursing health history**, a detailed database that allows you to plan and carry out nursing care to meet the client's needs. Box 12-1 presents guidelines for documenting a comprehensive history. This approach encourages you to focus on your client's strengths and available supports, as well as on the presenting problem.

As you collect data, you begin to categorize cues, make inferences, and identify emerging patterns, potential problem areas, and solutions. To do this well, you critically anticipate patterns, problems, and solutions, which means you try to stay a step ahead of the assessment. Before you make an inference, remember to document cues that support the inference. Your inferences will direct you to further questions. Once you ask a question of a client or make an observation, the information "branches" to an additional series of questions or observations (Figure 12-3). If you do not anticipate assessment questions, your assessment may be incomplete, or you may fail to recognize cues and dismiss relevant problem areas. Knowing how to probe and frame questions is a skill that you hone with experience. You learn to decide which questions are relevant to a situation and to interpret the data accurately.

Types of Data

Data can be obtained from two primary sources: subjective and objective. **Subjective data** are your clients' verbal descriptions of their health problems. Only clients provide subjective data. For example, Ms. Devine's report of back pain and her expression of dread over anticipating surgery are subjective findings. Subjective data usually include feelings, perceptions, and self-report of symptoms. Although only clients provide subjective data relevant to their health condition, be aware that the data sometimes reflect physiological changes, which you further explore through objective data collection.

Objective data are observations or measurements of a client's health status. Inspection of the condition of a wound, a description of an observed behaviour, and the measurement of blood pressure are examples of objective data. The measurement of objective data is based on an accepted standard, such as the Celsius measure on a thermometer, centimetres on a measuring tape, or known characteristics of behaviours (e.g., anxiety or fear). When you collect objective data, apply critical thinking intellectual standards (e.g., whether the data are clear, precise, and consistent) so that you can correctly interpret your findings.

Sources of Data

As a nurse, you obtain data from a variety of sources. Each source of data provides information about the client's level of wellness, strengths, anticipated prognosis, risk factors, health practices and goals, and patterns of health and illness.

Client. A client is usually your best source of information. Clients who are conscious, alert, and able to answer questions correctly provide the most accurate information about their health care needs, lifestyle patterns, current and past illnesses, perception of symptoms, and changes in activities of daily living. Consider the setting for your assessment. A client experiencing acute symptoms in an emergency department will not offer as much information as one who comes to an outpatient clinic for a routine checkup. Always be attentive, and show a caring presence with the client (see Chapter 18). Let the client

Figure 12-3 Example of branching logic for selecting assessment questions.

know you are interested in what he or she has to say. Clients are less likely to reveal the nature of their health care problems fully when nurses show little interest or are easily distracted by activities around them.

Family and Significant Others. Family members and significant others are primary sources of information for infants or children, critically ill adults, and mentally handicapped, disoriented, or unconscious clients. In cases of severe illness or emergency situations, families are sometimes the only available sources of information for nurses and clients' health care providers. The family and significant others are important secondary sources of information. They confirm findings that a client provides (e.g., whether a client takes medications regularly at home or how well the client sleeps or eats). Include interviewing the family when appropriate.

► BOX 12-1

Guidelines for Documenting a Comprehensive Nursing Health History

A. Identifying Data

Name, age, sex, date, and place of birth

B. Source of History

Relationship to client, any special circumstances such as use of interpreter

C. Reason for Health History Interview

Explain why you are interviewing the client at the present time (e.g., the client has just been admitted to an inpatient unit or clinic).

D. Current State of Health

General state of physical, mental, social, and spiritual health and health goals. If an illness is present, gather data about the nature of the illness by conducting a symptom analysis (see Chapter 31).

E. Developmental Variables

- Relationship status: single, married, partner, separated, widowed, divorced
- Number of children
- Developmental stage (see Chapter 21)
- Current occupation
- Significant life experiences (e.g., education, previous occupations, financial situations, retirement, coping or stress tolerance, and measures normally used to reduce stress)
- Safety hazards (e.g., biological, chemical, ergonomic, physical, psychosocial, reproductive)
- Housing, environmental hazards (e.g., type of housing, location, living arrangements; specific hazards in the home or community)
- Safety measures (e.g., use of seat belts, helmets, presence of smoke detectors and fire extinguishers, and other measures related to specific hazards of work, community, and home)

F. Psychological Variables

Mental processes, relationships, support systems, statements regarding client's feelings about self

G. Spiritual Variables (see Chapter 27)

Rituals, religious practices, beliefs about life, client's source of guidance in acting on beliefs, and the relationship with family in exercising faith

H. Sociocultural Variables

- Culture: values, beliefs and practices related to health and illness (see Chapter 9)
- Primary language and other languages spoken
- Recreation (exercise, hobbies, socializing, use of leisure time)
- Family and significant others, such as authorized representative, i.e., enduring power of attorney. Include family composition, relationships, special problems experienced by family, client's and family's response to stress, roles, and support systems. The family history provides information about family structure, interaction, and function that may be useful in planning care. For example, a cohesive, supportive family can help a client adjust to an illness or disability and should be incorporated into the plan of care. However, if the client's family members are not supportive, it may be better not to involve them in care. Outline a family tree (genogram; see Chapter 19) to determine whether the client is at risk for genetic illnesses and to identify areas of health promotion and illness prevention.

I. Physiological Variables (Body Structure and Function)**History of Past Illnesses and Injuries**

Including dates

Current Medications

Prescribed, over-the-counter, or illicit drugs. Include name, dosage, schedule, duration of and reason for use, and expected effects and side effects; if illicit drug, include type, amount, response, adverse reaction, drug-related accidents or arrests, attempts to quit.

Review of Systems

The **review of systems** is a systematic method for collecting data on all body systems. Not all questions in each system may be covered in every history. Nevertheless, some questions about each system are included, particularly when a client mentions a symptom or sign. The nurse begins with questions about the usual functioning of each body system and any noted changes and follows with specific questions such as the ones noted as follows for each system. Nurses also focus on measures taken by the client to promote and maintain health and those to prevent illness or injury. The following are included in the review of systems:

- **General manifestation of symptoms:** fever, chills, malaise, pain, sleep patterns and disturbances, fatigue, recent alterations in weight
- **Integumentary:** itching, colour or texture change, lesions, dryness and use of creams or lotions, changes in hair or nails
- **Ocular:** visual acuity, blurring, eye pain, recent change in vision, discharge, excessive tearing, date of last examination
- **Auditory:** hearing loss, pain, discharge, dizziness, perception of ringing in ears, wax
- **Upper respiratory:** nosebleeds, nasal discharge, nasal allergies, sinus problems, frequency of colds and usual method of treatment, sore throat and usual type of home remedy, hoarseness or voice changes
- **Lower respiratory:** use of tobacco (amount and number of years of smoking; exposure to tobacco smoke; if smoker, attempts to stop smoking), exposure to airborne pollutants, cough, sputum, wheezing, shortness of breath, tuberculosis test and results, date of last chest X-ray examination
- **Breasts and axillae:** rashes, lumps, discharge, pain, breast self-examination practices
- **Lymphatic:** pain, swelling
- **Cardiovascular:** chest pain or distress, precipitating causes, timing and duration, relieving factors, dyspnea, orthopnea, edema, hypertension, exercise tolerance, circulatory problems, varicose veins
- **Gastrointestinal:** appetite, digestion, food intolerance, dysphagia, heartburn, abdominal pain, nausea or vomiting, bowel regularity, use of laxatives, change in stool colour or contents, constipation or diarrhea, flatulence, hemorrhoids, rectal examinations
 - a. Dietary pattern: calculate number of servings per day of each of the food groups, using *Canada's Food Guide to Healthy Eating* (<http://www.nms.on.ca/pdfs/Food%20Guide.pdf>) for serving size (see Chapter 42); restrictions to food choice; special diets; use of salt; calculate adequacy of fluid intake (should be 30 to 40 mL of fluid per kilogram of body weight); indicate sources of calcium and amounts per day; alcohol use (average number of ounces per week, recent changes in pattern of consumption)
- **Urinary:** painful urination; blood, stones, or pus in urine; bladder or kidney infections; difficulty stopping urinary stream; dribbling or hesitancy; sudden feeling of need to urinate; frequent urination; nocturia (having to get up to void during the night); incontinence (see Chapter 43).
- **Genital and reproductive:**
 - a. Male: puberty onset, difficulty with erections, emissions, testicular pain, libido, infertility, urethral discharge, genital lesions, exposure to and history of sexually transmitted

Continued

► BOX 12-1 Guidelines for Documenting a Comprehensive Nursing Health History—cont'd

- infections, testicular self-examinations, testicular lump or pain, hernias, sexual preference, birth control method, and safer sex practices used
- b. Female: menses (onset, duration, regularity, flow, discomfort, date of most recent menstrual period), age at menopause (occurrence of hot flashes, night sweats, vaginal discharge), date of last Pap smear, pregnancies (number, miscarriages, abortions), exposure to and history of sexually transmitted infections, sexual preference, birth control method, and safer sex practices used
- **Musculoskeletal:** pain, joint stiffness or swelling, restricted motion, muscle wasting, weakness, general mobility, use of mobility aids, ability to perform activities of daily living
- **Neurological:** injury, headaches, dizziness, fainting, abnormalities of sensation or coordination, tremors, seizures
- **Endocrine:** excessive sweating, thirst, hunger, or urination; intolerance of heat or cold; changes in distribution of facial hair; thyroid enlargement or tenderness; unexplained weight change; change in glove or shoe size
- **Hematological:** anemia; bruise or bleed easily; transfusions
- **Psychiatric:** depression, mood changes, difficulty concentrating, nervousness, anxiety, suicidal thoughts, irritability
- **Immunological:** communicable diseases (indicate disease and age at or year of onset), immunization status (indicate year of most recent immunization), allergies (known allergens and reactions; MedicAlert identification worn)

Adapted from Skillen, D. L., & Day, R. A. (2004). *A syllabus for adult health assessment*. Edmonton: University of Alberta, Faculty of Nursing.

Remember that a client does not always wish you to question the family.

Spouses or close friends often sit in during an assessment and provide their view of the client's health problems or needs. They not only supply information about the client's current health status but are able to tell when changes in the client's status occurred. Family members are often well informed because of their experiences living with the client and observing how health problems affect daily living activities. Family and friends make important observations about the client's needs that can affect the way care is delivered (e.g., how a client eats a meal or how a client makes choices).

Health Care Team. You frequently communicate with other health care team members in gathering information about clients. In the acute care setting, the change-of-shift report is the way for nurses from one shift to communicate information to nurses on the next shift (see Chapter 15). When nurses, physicians, physiotherapists, social workers, or other staff consult about a client's condition, they typically have information about the client. This information may include how the client is interacting within the health care environment, the client's physical or emotional reactions to treatment, the result of diagnostic procedures or therapies, and how the client responds to visitors. Every member of the team is a source of information for identifying and verifying information about the client.

Medical Records. The medical record is a source of the client's medical history, laboratory and diagnostic test results, current physical findings, and the medical treatment plan. Data in the records offer baseline and ongoing information about the client's response to illness and progress to date. Information in a client's record is confidential. The medical record is a valuable tool for checking the consistency and similarities of personal observations.

Literature. You complete your assessment database by reviewing nursing, medical, and pharmacological literature about a client's present health status. This review increases your knowledge about the client's diagnosed problems, expected symptoms, treatment, prognosis, and established standards of therapeutic practice. A knowledgeable nurse obtains relevant, accurate, and complete information for the assessment database.

Nurse's Experience. Benner et al. (2010) assert that integration of evidence-based knowledge and good clinical

reasoning is essential to elicit and process information that will lead the nurse to deliver relevant therapeutic interventions. A nurse's expertise develops after testing and refining propositions, questions, and principle- or standard-based expectations. For example, after Lisa has cared for Ms. Devine, she has learned some lessons. Lisa will more quickly recognize the behaviour the client showed while in acute pain when she cares for the next client with similar health problems. Lisa will also note how positioning techniques helped Ms. Devine relax and ameliorated her discomfort. Practical experience and the opportunity to make clinical decisions strengthen your critical thinking.

Methods of Data Collection

As a nurse, you use the client interview, nursing health history, physical examination findings, and results of laboratory and diagnostic tests to establish a client's assessment database.

Interview. The first step in establishing a database is to collect subjective information by interviewing the client. An **interview** is an organized conversation with the client. The initial formal interview involves obtaining the client's health history and information about the current illness. During the initial interview, you have the opportunity to do the following:

- Introduce yourself to the client, explain your role, and explain the role of other health care providers during care.
- Establish a caring therapeutic relationship with the client.
- Obtain insight about the client's concerns and worries.
- Determine the client's goals and expectations of the health care system.
- Obtain cues about which parts of the data collection phase necessitate further in-depth investigation.

You and the client become partners during the interview, rather than you controlling the interview. An interview consists of three phases, similar to that of a therapeutic relationship: orientation, working, and termination.

A successful interview requires preparation. Collect any available information about the client, and then create a favourable environment for the interview. An environment in which the client is comfortable and relaxed helps you conduct a good interview. Some clients interviewed at home prefer that the interview take place in a bedroom, away from other family members, or in the living room, with a spouse present. Remember to let a client decide whether to involve the family. Finally,

select a place private enough to allow the client to be comfortable when providing personal information.

Orientation Phase. During the orientation phase of the interview, you introduce yourself, describe your position, and explain the purpose of the interview. Explain to clients why you are collecting data (e.g., for a nursing history or for a focused assessment) and assure them that any information obtained will remain confidential and will be used only by health care providers.

After making Ms. Devine more comfortable, Lisa decides that it is time to get to know her client better. Lisa reviews the interview process and its objectives, confidentiality, and length. "I want to spend some time better understanding your back pain and then what you know about your surgery. If you are comfortable, I would like to spend about 10 minutes discussing this with you. Everything you share will be confidential." Lisa and Ms. Devine agree mutually on the interview time.

LISA: Now, I want to ask you some questions about your health so we can plan your care together. Before we get started, do you have any questions for me?

MS. DEVINE: Yes. I know they plan to remove the disc in my back. It has been hurting so bad. I can't even bend over. Is there a chance I could be paralyzed?

LISA: Tell me what your doctor has explained about surgery.

MS. DEVINE: She has told me that I have a, what was it called, a herniated disc. She said it is pinching nerves in my back. Well, if it pinches nerves, could I not become paralyzed? She did tell me that she has done this procedure many times before.

LISA: A herniated disc is serious. The disc is normally situated between two vertebrae, but in your case it is now pinching on your spinal nerves. That is why you have so much discomfort. Your surgery is aimed at removing pressure on your nerves. I would suggest you talk with your doctor about your concerns before going into surgery.

MS. DEVINE: Okay, that makes me feel a little better. I have some important things going on at my work. My husband and I own our own business. I just want this to be over.

LISA: Tell me more about your pain.

Working Phase. In the working phase of the interview, you gather information about the client's health status. Remember to stay focused, orderly, and unhurried. Use a variety of communication strategies such as active listening, paraphrasing, and summarizing to promote a clear interaction (see Chapter 17). The use of open-ended questions encourages clients to describe their health histories in detail.

Use **open-ended questions** whenever you are not sure what the answer will be and when you want the description in the client's own words (Box 12-2). Remember that **closed-ended questions** can all be answered by yes or no (or a choice of answers that you provide), and limit these to issues in which you do not need additional information from the client.

During the working phase, obtain a nursing health history by exploring the client's current illness, health history, and expectations of care. The objective for collecting a health history is to identify patterns of health and illness, risk factors for physical and behavioural health problems, changes from normal function, and available resources for adaptation. The initial interview is normally the most extensive. Ongoing interviews, which occur each time you interact with your client, do not need to be as extensive; their purpose is to update the client's status and focus more on changes in previously identified ongoing and new problems. An example of Lisa's interview techniques is as follows:

► BOX 12-2

Examples of Open- and Closed-Ended Questions

Open-Ended Questions

Tell me how you are feeling.

Your discomfort affects your ability to get around in what way?

Describe how your wife has been helping you.

Give me an example of how you get relief from your pain at home.

Closed-Ended Questions

Do you feel as if the medication is helping you?

Who is the person who helps you at home?

Do you understand why you are having the X-ray examination?

Has the warm compress given you relief from your back pain?

Are you having pain now?

On a scale of 0 to 10, how would you rate your pain?

LISA: Tell me, Ms. Devine, about your back pain. [Open-ended question]

MS. DEVINE: Sometimes it is really sharp, especially when I stand and try to walk.

LISA: On a scale of 0 to 10, with 0 being no pain and 10 being the worst imaginable, how would you rate your pain when it becomes sharp? [Close-ended question]

MS. DEVINE: Oh, it can be bad; I would rate it an 8 or 9.

LISA: Point to where you notice the pain. [Asking for specificity]

MS. DEVINE: [points to her lower sacral area] It hurts here, and I also get a deep burning pain in my right buttock.

LISA: Can you tell me if anything else aggravates the pain?

MS. DEVINE: This morning I sneezed and thought I was going to faint. Then I could feel the pain go down my right leg.

LISA: Does anything else worsen the pain? [Probes for completeness]

MS. DEVINE: Well, just about any way I move tends to make my back hurt.

LISA: Any way? [Clarification]

MS. DEVINE: It hurts when I turn or twist. If I lie flat, it does not bother me.

LISA: In what way has it limited you in your usual activities? [Open-ended question]

MS. DEVINE: Well, I have not been able to work. I went back about a month ago, but I was miserable when I tried to sit down. I could not tolerate the discomfort.

Termination Phase. As in the other phases of the interview, termination requires skill on the part of the interviewer. Give your client a clue that the interview is coming to an end. For example, say, "I want to ask just two more questions" or "We'll be finished in about two minutes." This helps the client maintain direct attention without being distracted by wondering when the interview will end. This approach also gives the client an opportunity to ask questions. When concluding an interview, summarize the important points and ask the client whether the summary was accurate. End the interview in a friendly manner, telling the client when you will return to provide care; for example:

"Thank you, Ms. Devine. You have given me a good picture of your back problem and what you have been told about surgery. I think pain control will be a priority before and after your surgery. Because this is your first time in the hospital, I want to be sure I explain whatever

you would like to know. I am going to return in about an hour and talk with you about the surgery and what to expect. Can I do anything for you now?"

A skillful interviewer adapts interview strategies on the basis of the client's responses. You successfully gather relevant health data when you are prepared for the interview, and you are able to carry out each interview phase with minimal interruption.

Cultural Considerations in Assessment

As a professional nurse, it is important to conduct any assessment with cultural competence and cultural safety (see Chapter 9). This involves a conscientious understanding of your client's culture so that you can offer better care within differing value systems and act with respect and understanding without imposition of your own attitudes and beliefs (Seidel et al., 2011). Good communication techniques are important when assessing a client whose culture is different from your own. Communication and culture are interrelated in the way feelings are expressed verbally and nonverbally. If you can learn the variations in how people of different cultures communicate, you will probably be able to gather more accurate information from clients. For example, the Spanish and French use firm eye contact when speaking. However, this is considered rude or immodest by certain Asian or Middle Eastern cultures. North Americans often tend to let the eyes wander (Seidel et al., 2011). By using the right approach with eye contact, for example, you demonstrate respect for your client, and the client is probably encouraged to share more information.

When you interact to assess any specific client, first know your own cultural self. Cultural awareness can be achieved by engaging in self-reflection of your biases and feelings (see Chapter 9). You need to avoid forming a sense of the client on the basis of prior information about the client's culture. Instead, draw upon your knowledge and then ask questions in a constructive and probing way to allow you to truly understand the client.

Nursing Health History

You conduct a nursing health history during either your initial contact or an early contact with a client. The history is a major component of assessment. Although many health history forms are structured, you learn to use the questions as starting points. A good assessor learns to refine and broaden questions as needed in order to correctly assess the client's unique needs. Time and client priorities determine how complete a history is. Identify patterns of information about a client's health and illness by collecting data about all health dimensions (see Box 12-1). Incorporating data from all dimensions allows you to develop a complete plan of care.

Family History

The purpose of collecting the family history is to obtain data about immediate and blood relatives. The objectives are to determine whether the client is at risk for illnesses of a genetic or familial nature and to identify areas of health promotion and illness prevention (see Chapter 20). The family history also provides information about family structure, interaction, and function that is often useful in planning care (see Chapter 19). For example, a close, supportive family will help a client adjust to an illness or disability, and so you incorporate information from the family into the plan of care. If the client's family is

not supportive, however, it is better to not involve family members in care. Stressful family relationships are sometimes a significant barrier when you try to help clients with problems involving loss, self-concept, spiritual health, and personal relationships.

Documentation of History Findings

As you conduct the nursing health history, record your assessment in a clear, concise manner, using appropriate terminology. Standardized forms make it easy to enter data as the client responds to questions. In settings that have computerized documentation, entry of assessment data is very easy. A clear, concise record is necessary for use by other health care providers (see Chapter 15). Regardless of the model used in a documentation system, you want a thorough database that provides historical and current information about the client's health. This information then becomes the baseline against which you evaluate any future changes.

Physical Examination

A physical examination is an investigation of the body to determine its state of health. A physical examination involves use of the techniques of inspection, palpation, percussion, auscultation, and smell (see Chapter 31). A complete examination includes measurements of a client's height, weight, and vital signs and a head-to-toe examination of all body systems. By performing actual hands-on physical assessment, you gather valuable objective information that helps in forming accurate diagnostic conclusions. Always conduct an examination with sensitivity and competence to prevent your client from becoming anxious.

Observation of Client Behaviour. Throughout an interview and physical examination, it is important for you to observe a client's verbal and nonverbal behaviours closely. The information enhances your objective database. You learn to determine whether data obtained by observation matches what the client verbally communicates. For example, if a client expresses no concern about an upcoming diagnostic test but shows poor eye contact, shakiness, and restlessness, all suggestive of anxiety, then verbal and nonverbal data conflict. Observations direct you to gather additional objective information to form accurate conclusions about the client's condition. An important aspect of observation includes a client's level of function: the physical, developmental, psychological, and social aspects of everyday living. Observation of the level of function differs from observations you make during an interview. Observation of level of function involves watching what a client does, such as eating or making a decision about preparing a medication, rather than what the client tells you he or she can do. Observation of function can occur in the home or in a health care setting during a return visit.

Diagnostic and Laboratory Data. The results of diagnostic and laboratory tests reveal or clarify alterations questioned or identified during the nursing health history and physical examination. For example, during the history documentation, the client reports having a bad cold for six days and at present has a productive cough with brown sputum and mild shortness of breath. On physical examination, you notice an elevated temperature, increased respirations, and decreased breath sounds in the right lower lobe. You review the results of a complete blood cell count and note that the white blood cell count is elevated (indicating an infection). In addition, the radiologist's report of a chest X-ray examination shows the

presence of a right lower lobe infiltrate. Such findings combined are suggestive of the medical diagnosis of pneumonia and the associated nursing diagnosis of *impaired gas exchange*.

Some clients collect and monitor laboratory data in the home. For example, clients with diabetes mellitus often perform daily blood glucose monitoring. Ask clients about their routine results to determine their responses to illness and elicit information about the effects of treatment measures. Compare laboratory data with the established norms for a particular test result, age group, and gender.

Interpreting Assessment Data and Making Nursing Judgements.

The successful analysis and interpretation of assessment data requires critical thinking. When you correctly analyze data, you recognize patterns that lead you to make necessary clinical decisions about your client's care. These decisions are in the form of either nursing diagnoses or collaborative problems that require treatment from several disciplines (Carpenito-Moyet, 2008). When you critically think about interpreting assessment information, you determine the presence of abnormal findings, what further observations you need to clarify information, and the client's health problems.

Data Validation. Before you begin analyzing and interpreting data, validate the collected information you have, in order to avoid making incorrect inferences (Carpenito-Moyet, 2008). **Validation** of assessment data is the comparison of data with another source to determine data accuracy. For example, you observe a client crying and logically infer it is related to hospitalization or a medical diagnosis. Making such an initial inference is not wrong, but problems result if you do not validate the inference with the client. Instead, say, "I notice that you have been crying. Can you tell me about it?" By questioning the client, you will discover the real reason for the crying behaviour. Ask your client to validate the information obtained during the interview and history. Validate findings from the physical examination and observation of client behaviour by comparing data in the medical record and by consulting with other nurses or health care team members. Often family or friends are able to validate your assessment information. Validation opens the door for gathering more assessment data because it involves clarifying vague or unclear data. On occasion, you need to reassess previously covered areas of the nursing history or gather further physical examination data. Continually analyze and think about a client's database to make concise, accurate, and meaningful interpretations. Critical thinking applied to assessment enables you to fully understand the client's problems, to judge the extent of the problems carefully, and to discover possible relationships between the problems.

Lisa gathered initial data about the character of Ms. Devine's back pain. She applied critical thinking in her assessment as she considered what she knew about ruptured lumbar discs and the anticipated type of symptoms that clients experience. As she assessed Ms. Devine, she applied intellectual standards, obtaining information that was precise (location of pain), consistent and accurate (use of pain rating scale), and complete (probing for factors that worsen pain). Lisa learned additional information about Ms. Devine's concerns about surgery. Ms. Devine tells Lisa, "I hope the surgery goes well. You know, I have a friend who had back surgery, and she took a long time to recover. I want to get back to work without a long absence. If this had just not happened—why did I have to fall?" Lisa could make several inferences from this information, but she applies the critical thinking attitude of discipline and stays

► BOX 12-3 Steps of Data Analysis

1. Recognize a pattern or trend by cues:
 - Turns slowly
 - Is unable to bend over
 - Walks with hesitation
2. Compare with normal standards:
 - Has normal range of motion
 - Initiates movement without hesitation
3. Make a reasoned conclusion:
 - Has limited mobility
 - Has reduced activity level

focused to ensure her assessment is accurate and comprehensive. She validates her inferences with Ms. Devine: "You sound anxious about having surgery. You know of others who have had difficult outcomes after surgery. Do you think you are uncertain about what to expect?" Ms. Devine confirms Lisa's assessment: "Yes, I am worried. I have never been in a hospital, as you know, and I feel I do not know what that involves. I am a person who likes to have information, so I can make the right decisions and know what to do."

Analysis and Interpretation. After you collect extensive information about a client, you analyze and interpret the data. You begin analysis by organizing the information into meaningful and usable clusters, keeping in mind your client's response to illness. A data cluster is a set of signs or symptoms that you group together in a logical way. During data clustering, organize data and focus attention on client functions for which support or assistance for recovery is needed. **Data analysis** involves recognizing patterns or trends in the clustered data, comparing them with standards, and then establishing a reasoned conclusion about the client's responses to a health problem (Box 12-3). Patterns of meaning begin to form, enabling you to make inferences about client problems.

Through reasoning and judgement, you decide what information explains the client's health status. At times, you need to gather additional information to clarify your interpretation. For example, Ms. Devine told Lisa that she had not been in a hospital and did not know what that involved. Lisa inferred or guessed that Ms. Devine had limited knowledge about the laminectomy and the associated nursing care. Instead of making that conclusion, Lisa sought further information by asking, "Tell me what your doctor has told you about your surgery." Ms. Devine related, "Well, I know the doctor is going to remove something between my vertebrae. She said I will be in the hospital about two or three days." Lisa asked, "Has anyone talked with you about your care after surgery?" Ms. Devine replied, "No, not really. I have several questions I would like to ask about it." Lisa listened to the additional information provided by Ms. Devine. In looking for patterns of data, Lisa decided that Ms. Devine had a knowledge deficiency because of her limited preparation for the surgery but was interested in learning. If you are successful in clustering data well in your analysis, you will become proficient in identifying individualized nursing diagnoses and in identifying collaborative problems (see Figure 12-6).

During clustering, a cue or an individual sign, symptom, or finding will alert you more than others do. Such cues are especially helpful in identifying nursing diagnoses. In time, you will become experienced in recognizing clusters that indicate problems such as pain, anxiety, or immobility.

Figure 12-4 Concept map for Ms. Devine's nursing assessment findings.

Data Documentation

Data documentation is the last part of a complete assessment. The timely, thorough, and accurate documentation of facts is necessary when clients' data are recorded. If you do not record an assessment finding or problem interpretation, that information is lost and unavailable to anyone else caring for the client. If specific information is lacking, the person reading the report is left with only general impressions. Observation and recording of client status is a legal and professional responsibility. Recording factual information is easy after it becomes a habit. The basic rule is to record all observations. When you record data, pay attention to facts, and make an effort to be as descriptive as possible. Anything heard, seen, felt, or smelled should be reported exactly. Record objective information in accurate terminology (e.g., "weighs 77.3 kg," "abdomen is soft and non-tender to palpation"). Record subjective information from a client in quotation marks. When entering data, do not generalize or form judgements through written communication. Conclusions about such data become nursing diagnoses and thus must be accurate. As you gain experience and become familiar with clusters and patterns of signs and symptoms, you will conclude the existence of the correct problem. Clustering helps make documentation more concise and focused. (Review Chapter 15 for details on documentation.)

Concept Mapping

Most of the clients you care for have more than one health problem. A **concept map** is a visual representation that allows you to graphically show the connections between a client's

health problems. It promotes critical thinking by fostering a holistic view of the client and identifying linkages between the multiple problems affecting the client (Hicks-Moore & Pastirik, 2006). Concept mapping may help nursing students bridge the gap between theory and practice in the clinical setting (Senita, 2008). The visual image of clients as holistic, multidimensional, and complex serves as a starting point for the development of a comprehensive, individualized care plan (Taylor & Wros, 2007).

Figure 12-4 shows the first step in a concept map that Lisa will develop for Ms. Devine as a result of her nursing assessment.

Nursing Diagnosis

After you assess a client thoroughly to compile a database, the next step of the nursing process is to form diagnostic conclusions that determine the nursing care that a client receives (Figure 12-5). Some of the conclusions lead to nursing diagnoses, whereas others do not. Diagnostic conclusions include problems treated primarily by nurses (nursing diagnoses) and problems necessitating treatment by several disciplines (collaborative problems). For both nursing diagnoses and collaborative problems, the nurse makes independent decisions (Carpenito-Moyet, 2008).

When physicians refer to commonly accepted medical diagnoses, such as myocardial infarction, diabetes mellitus, or osteoarthritis, they all know the meaning of the diagnoses and the standard approaches to treatment. A **medical diagnosis** is the identification of a disease condition on the basis of a

Figure 12-5 Critical thinking and the nursing diagnostic process.

specific evaluation of physical signs, symptoms, the client's medical history, and the results of diagnostic tests and procedures. Physicians are licensed to treat diseases or pathological processes described in medical diagnostic statements. Nurses have a similar diagnostic language. **Nursing diagnosis**, the second step of the nursing process, determines health problems within the domain of nursing. The process of diagnosing is the result of your analysis of data and your resultant identification of specific client responses to health care problems. The term *diagnose* means "distinguish" or "know." A nursing diagnosis is a clinical judgement about individual, family, or community responses to actual and potential health problems or life processes that is within the domain of nursing (NANDA International, 2009). Box 12-4 shows examples of NANDA International Nursing Diagnoses.

A **collaborative problem** is an actual or potential physiological complication that nurses monitor to detect the onset of changes in a client's status (Carpenito-Moyet, 2008). When collaborative problems develop, nurses intervene in collaboration with personnel from other health care disciplines. Nurses manage collaborative problems such as hemorrhage, infection, and cardiac dysrhythmia by using both physician-prescribed and nursing-prescribed interventions to minimize complications. For example, a client who has a surgical wound is at risk for developing an infection, and so a physician prescribes antibiotics. The nurse monitors the client for fever and other signs of infection and implements appropriate wound care measures.

clusters and patterns of data she collected to correctly identify the nursing diagnoses that apply to Ms. Devine's situation. One cluster of data includes information about Ms. Devine's inexperience with surgery and her statement that she has not received information about postoperative activities. Lisa decides that the data include defining characteristics for the nursing diagnosis deficient knowledge regarding postoperative routines related to inexperience. Lisa has been assigned to care for the client on the day after surgery. Lisa knows from experience that common postoperative collaborative problems include wound infection and acute urinary retention. Lisa will work closely with the physician and other members of the nursing team in an effort to prevent or minimize these problems. Ms. Devine's health care plan will include a combination of interventions directed to resolve or manage nursing and medical diagnoses and any related collaborative problems.

Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which you, as a nurse, are accountable (NANDA International, 2009). A nursing diagnosis focuses on a client's actual or potential response to a health problem rather than on the physiological event, complication, or disease. In the case of the diagnosis *deficient knowledge regarding postoperative routines*, Lisa will offer instruction to improve Ms. Devine's knowledge of what to expect after surgery and how she is able to participate in her postoperative care. A nurse cannot independently treat a medical diagnosis such as a herniated disc. However, Lisa will manage Ms. Devine's postoperative care, monitoring her postoperative progress and managing wound care, fluid administration, and medication therapy to prevent collaborative problems from developing. Collaborative problems occur or probably will occur in association with a specific disease, trauma, or treatment (Carpenito-Moyet, 2008). You will need expert nursing knowledge to assess a client's specific risk for these problems,

Ms. Devine is scheduled to undergo a lumbar laminectomy for a herniated lumbar disc (her medical diagnosis). Lisa has conducted an assessment of Ms. Devine's health status and needs and has collected information in four different problem areas. Lisa then reviews the

► BOX 12-4 Examples of NANDA International Nursing Diagnoses

Activity intolerance	Constipation
Risk for activity intolerance	Perceived constipation
Ineffective airway clearance	Risk for constipation
Latex allergy response	Contamination
Risk for latex allergy response	Risk for contamination
Anxiety	Compromised family coping
Death anxiety	Defensive coping
Risk for aspiration	Disabled family coping
Risk for impaired parent-child attachment	Ineffective coping
Autonomic dysreflexia	Ineffective community coping
Risk for autonomic dysreflexia	Readiness for enhanced coping
Risk-prone health behaviour	Readiness for enhanced community coping
Disturbed body image	Readiness for enhanced family coping
Risk for imbalanced body temperature	Risk for sudden infant death syndrome
Bowel incontinence	Readiness for enhanced decision making
Effective breastfeeding	Ineffective denial
Ineffective breastfeeding	Impaired dentition
Interrupted breastfeeding	Risk for delayed development
Ineffective breathing pattern	Diarrhea
Decreased cardiac output	Risk for compromised human dignity
Caregiver role strain	Moral distress
Risk for caregiver role strain	Risk for disuse syndrome
Readiness for enhanced comfort	Deficient diversional activity
Impaired verbal communication	Disturbed energy field
Readiness for enhanced communication	Impaired environmental interpretation syndrome
Decisional conflict	Adult failure to thrive
Parental role conflict	Risk for falls
Acute confusion	Dysfunctional family processes: alcoholism
Chronic confusion	Interrupted family processes
Risk for acute confusion

to identify the problems early, and then to take preventive action (Figure 12-6). Critical thinking is necessary in identifying nursing diagnoses and collaborative problems so that you individualize care appropriately for your clients.

Nursing diagnosis is recognized in Canada as an innovative means of translating nursing observations and assessments into standard conclusions in a common nomenclature. Although nursing diagnosis is part of basic nursing preparation in Canada, it has not yet been incorporated into provincial and territorial nursing practice standards or legislation. The Canadian Nurses Association (CNA) (2012) describes the competencies required of registered nurses in the area of assessment and diagnosis in the following statements taken from the list of competencies required of nurses for professional practice:

- The registered nurse:
- HW-7 Collaborates with other health care team members to implement strategies that prevent violence, abuse, and neglect (e.g., using screening tools, providing information)
- HW-15 Takes action to address actual or potential risk factors related to health (e.g., food access, unsafe sexual practices, inactivity, smoking)
- HW-16 Takes action to address actual or potential environmental risk factors (e.g., incidents and accidents, environmental contaminants, mechanical equipment, infectious diseases)

- HW-19 Incorporates determinants of health into the plan of care (e.g., adequate income, food and water safety, adequate housing, and shelter)
- HW-27 Uses data collection techniques that are appropriate to the client and the situation (e.g., community assessment, assessment tools)
- CH-1 Collaborates with clients in a holistic assessment (e.g., physical, emotional, mental, spiritual, cognitive, developmental, environmental, meaning of health) (Jurisdictional Collaborative Process, 2006)
- CH-3 Collects assessment data from a range of appropriate sources (e.g., the client, previous and current health records, nursing care plans, collaborative plans of care, family members, significant others, substitute decision makers, census data, epidemiological data, evidence-informed data, referrals, other health care providers)
- CH-4 Uses appropriate assessment techniques for data collection (e.g., observation, inspection, auscultation, palpation, percussion, selected screening tests, pain scales, interview, consultation, focus group, measuring and monitoring)
- CH-5 Validates data collected with the client and appropriate sources (e.g., medication reconciliation, health history, consultations, referrals)
- CH-6 Analyzes data to establish relationships and draw conclusions from the various data collected (e.g., determines

Figure 12-6 Differentiating nursing diagnoses from collaborative problems. **Source:** Copyright © 1990, 1988, 1985, by Lynda Juall Carpenito. Redrawn from Carpenito, L. J. (1995). *Nursing diagnosis: Application to clinical practice* (6th ed.). Philadelphia, PA: J. B. Lippincott.

relationship between health assessment and laboratory values)

- CH-8 Applies knowledge from health sciences (e.g., physiology, pathophysiology, psychopathology, pharmacology, microbiology, epidemiology, genetics, immunology, nutrition, sociology) (Jurisdictional Collaborative Process, 2006)
- CH-9 Identifies actual and potential changes in health (e.g., pain management, disability, immobility)
- CH-18 Facilitates physical, psychological, and psychosocial adjustment (e.g., therapeutic communication, counselling, appropriate referral, chronic disease management) (CNA, 2012)

It is clear from these statements regarding nursing competencies that nursing diagnosis is intrinsic to professional practice in Canada. The use of standard formal nursing diagnostic statements (see Box 12-4) serves several purposes:

1. They provide a precise definition that gives all members of the health care team a common language for understanding the client's needs.
2. They allow nurses to communicate their actions among themselves, to other health care providers, and to the public.
3. They distinguish the nurse's role from that of the physician or other health care providers.
4. They help nurses focus on the scope of nursing practice.
5. They foster the development of nursing knowledge.

Critical Thinking and the Nursing Diagnostic Process

Diagnostic reasoning is a process of using assessment data about a client to logically explain a clinical judgement: in this

case, a nursing diagnosis. The diagnostic process flows from the assessment process and includes decision-making steps. These steps include data clustering, identifying client needs, and formulating the diagnosis or problem.

Clusters and patterns of data often contain **defining characteristics**; the clinical criteria or assessment findings that help confirm an actual nursing diagnosis. **Clinical criteria** are objective or subjective signs and symptoms, clusters of signs and symptoms, or risk factors that lead to a diagnostic conclusion. A specific set of defining characteristics helps confirm identification of each **NANDA International**-approved nursing diagnosis (NANDA International, 2009). As a nurse, you learn to recognize patterns of defining characteristics and then readily select the corresponding diagnosis.

Table 12-1 shows two examples of approved nursing diagnoses and their associated defining characteristics. As you analyze clusters of data, begin to consider various diagnoses that might apply to your client. For example, the diagnoses of *impaired gas exchange* and *ineffective breathing pattern* have similar defining characteristics, including dyspnea, abnormal respiratory rate, and abnormal depth of breathing. When you determine a diagnosis, however, remember that the absence of certain defining characteristics suggests that you reject a diagnosis under consideration. Thus, in the same example, if a client uses accessory muscles to breathe and demonstrates pursed-lip breathing, the correct diagnosis is not *impaired gas exchange* but *ineffective breathing pattern*. Always examine the defining characteristics in your database carefully to confirm or eliminate a nursing diagnosis. To be more accurate, review all characteristics, eliminate irrelevant ones, and confirm the relevant ones.

▶ TABLE 12-1

Examples of NANDA International-Approved Nursing Diagnoses with Defining Characteristics

Diagnosis: Impaired Gas Exchange

Defining Characteristics

Dyspnea
Abnormal rate, rhythm, depth of breathing
Abnormal arterial pH
Abnormal skin colour (pale, dusky)
Hypoxemia
Hypercarbia

Hypoxia
Confusion

Diagnosis: Ineffective Breathing Pattern

Dyspnea
Bradypnea

Decreased vital capacity
Orthopnea
Altered chest excursion
Use of accessory muscles to breathe
Tachypnea
Pursed-lip breathing

Related Factors

Ventilation-perfusion
Alveolar-capillary membrane changes

Hyperventilation
Pain
Chest wall deformity
Anxiety
Musculoskeletal impairment
Body position

Data from NANDA International. (2009). *NANDA-I nursing diagnoses: Definitions and classification, 2009–2011*. Indianapolis, IN: Wiley-Blackwell.

While focusing on patterns of defining characteristics, you also compare a client's pattern of data with data that are consistent with normal, healthy patterns. Use accepted norms as the basis for comparison and judgement. These norms include laboratory and diagnostic test values, professional standards, and normal anatomical or physiological limits. When comparing patterns, judge whether the grouped signs and symptoms are normal for the client and whether they are within the range of healthy responses. Isolate any defining characteristics not within healthy norms in order to identify a problem.

Before finalizing a nursing diagnosis, review the client's general health care needs or problems. Identifying client needs allows you to individualize nursing diagnoses by considering all assessment data and focusing on the more relevant data. For example, after reviewing clusters of data from Ms. Devine's assessment, Lisa was able to recognize that the client had a knowledge deficiency. However, before Lisa was able to provide appropriate care, it was necessary to define Ms. Devine's problem more specifically. NANDA International (2009) has two nursing diagnoses that apply to knowledge: *deficient knowledge* and *readiness for enhanced knowledge*. A careful review of Ms. Devine's presenting behaviours and self-report of the problem led to the selection of *deficient knowledge* because the client had no previous knowledge of postoperative activities. Her problem was not a need for knowledge reinforcement but the absence of knowledge. It is crucial to select the correct diagnostic label for a client's need. Usually from assessment to diagnosis, the information that you gather progresses from general to specific. It helps to think of the problem identification phase in terms of the general health care problem and to think of the formulation of the nursing diagnosis in terms of the specific health problem.

Formulation of the Nursing Diagnosis

NANDA International (2009) identified four types of nursing diagnoses: actual diagnoses, risk diagnoses, health promotion diagnoses, and wellness diagnoses. An **actual nursing diagnosis** describes responses to health conditions or life processes that exist in an individual, family, or community. Defining characteristics (manifestations, signs, and symptoms) that cluster in patterns of related cues or inferences support this diagnostic judgement (NANDA International, 2009). The selection of an actual diagnosis indicates that sufficient assessment data are available to establish the nursing diagnosis. In the case of Ms. Devine, Lisa assessed the client to have back pain with a severity rated from 8 to 9 on a 10-point scale. The pain increased with movement. As a result of the pain, Ms. Devine has slept poorly. *Acute pain* is an actual nursing diagnosis. Prioritizing established nursing diagnosis is an important component of the nursing process (see Chapter 13).

A **risk nursing diagnosis** describes human responses to health conditions or life processes that will possibly develop in a vulnerable individual, family, or community (NANDA International, 2009). For example, after Ms. Devine undergoes the laminectomy, she has a surgical incision. The hospital environment poses a risk for infection. Thus, after Ms. Devine's surgery, Lisa chooses the nursing diagnosis *risk for infection*. The key assessment for this type of diagnosis is the presence of data that reveal risk factors (incision and hospital environment) that confirm Ms. Devine's vulnerability. Such data include physiological, psychosocial, familial, lifestyle, and environmental factors that increase the client's vulnerability to, or likelihood of developing, the condition.

A **health-promotion nursing diagnosis** is a clinical judgement of a person's, family's, or community's motivation and desire to increase well-being and actualize human health potential, as expressed in their readiness to enhance specific health behaviours, such as nutrition and exercise. Health-promotion diagnoses can be used in any health state; they do not reflect current levels of wellness (NANDA International, 2009).

A **wellness nursing diagnosis** describes levels of wellness in an individual, family, or community that can be enhanced (NANDA International, 2009). It is a clinical judgement about an individual, group, or community in transition from a specific level of wellness to a higher level of wellness. You select this type of diagnosis when the client wishes to or has achieved an optimal level of health. For example, readiness for enhanced coping related to successful cancer treatment is a wellness diagnosis, and the nurse and the family unit work together to adapt to the stressors associated with cancer survivorship. In doing so, the nurse incorporates the client's strengths and resources into a plan of care, with the outcome directed at improving the level of coping.

Components of a Nursing Diagnosis

The nursing diagnosis results from the assessment and diagnostic process. Throughout this text, nursing diagnoses are in a two-part format: the diagnostic label followed by a statement of a related factor (Table 12-2). It is this two-part format that provides a diagnosis meaning and relevance for a particular client. In addition, all NANDA International-approved diagnoses have a definition. Risk factors are a component of all risk nursing diagnoses.

Diagnostic Label. The **diagnostic label** is the name of the nursing diagnosis as approved by NANDA International

▶ TABLE 12-2

NANDA International (2009)
Nursing Diagnosis Format

Diagnostic Statement	Diagnostic Statement
Acute pain	Biological, chemical, physical, or psychological injury agents (e.g., inflammation, edema, burn)
Anxiety	Stress Unmet needs Interpersonal transmission
Impaired skin integrity	Situational or maturational crises Fluid retention Impaired skin integrity Excessive secretions Immobilizations Altered circulation

(2009) (see Table 12-1). It describes the essence of a client's response to health conditions in as few words as possible. Diagnostic labels include descriptors used to give additional meaning to the diagnosis. For example, the diagnosis *impaired physical mobility* includes the descriptor *impaired* to describe the nature or change in mobility that best describes the client's response. Examples of other descriptors are *compromised*, *decreased*, *deficient*, *delayed*, *effective*, *imbalanced*, *impaired*, and *increased*.

Related Factors. The **related factor** is a condition or **etiology** identified from the client's assessment data. It is associated with the client's actual or potential response to the health problem and can be changed through the use of nursing interventions. For example, in the case of Ms. Devine, Lisa assessed that Ms. Devine had not received instruction on postoperative activities and that Ms. Devine was asking questions. Lisa also learned that Ms. Devine had not undergone surgery before. The nursing diagnostic statement for Ms. Devine will include the diagnostic label (e.g., *deficient knowledge regarding postoperative routines*) and the related factor (e.g., *related to lack of exposure to instruction*) (Figure 12-7). Because of the related factor *lack of exposure to instruction*, Lisa will implement client instruction on postoperative activities. The "related to" phrase is not a cause-and-effect statement; rather, it indicates that the etiology contributes to or is associated with the client's diagnosis (Figure 12-8). The inclusion of the "related to" phrase requires you to use critical thinking skills to individualize the nursing diagnosis and then select nursing interventions (Table 12-3). The origin or cause of the nursing diagnosis is always within the domain of nursing practice and a condition that responds to nursing interventions.

Sometimes health care providers record medical diagnoses as the etiology in the nursing diagnosis. This is incorrect. Nursing interventions do not change a medical diagnosis. However, you direct nursing interventions at behaviours or conditions that you are able to treat or manage. For example, the nursing diagnosis *acute pain related to herniated disc* is incorrect; nursing actions do not affect the medical diagnosis of a herniated disc. Instead, a diagnosis of *acute pain related to pressure on spinal nerves* results in nursing interventions directed at reducing stress on the vertebrae, improving body alignment, and offering nonpharmacological comfort measures.

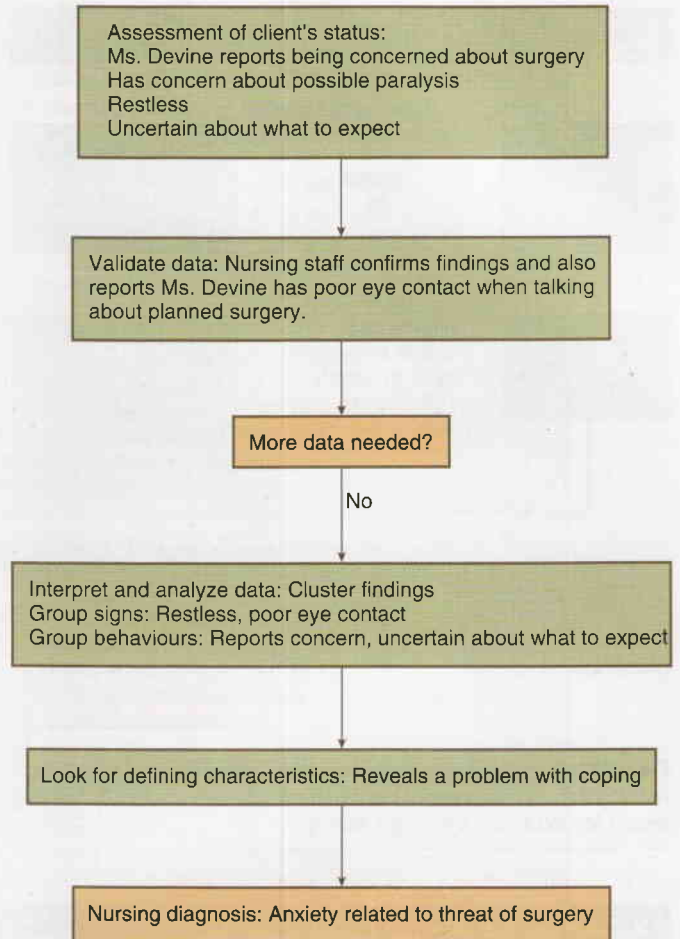

Figure 12-7 Diagnostic process for Ms. Devine.

Table 12-4 demonstrates the association between a nurse's assessment of a client, the clustering of defining characteristics, and formulation of nursing diagnoses. The diagnostic process results in the formation of a total diagnostic label that enables a nurse to develop an appropriate **client-centred plan of care**. The defining characteristics and relevant etiologies are from NANDA International (2009).

Definition. NANDA International (2009) approved a definition for each diagnosis that follows clinical use and testing. The definition describes the characteristics of the human response identified. For example, the definition of the diagnostic label *impaired physical mobility* is the "limitation in independent, purposeful physical movement of the body or of one or more extremities" (NANDA International, 2009). You will refer to definitions of nursing diagnoses to assist in identifying a client's correct diagnosis.

Risk Factors. Risk factors are environmental, physiological, psychological, genetic, or chemical elements that increase the vulnerability of an individual, family, or community to an unhealthful event (NANDA International, 2009). They are a component of all risk nursing diagnoses. The risk factors are cues to indicate that a risk nursing diagnosis is applicable to a client's condition. Examples of risk factors for the nursing diagnosis *risk for infection* include invasive procedures, trauma, malnutrition, immunosuppression, and insufficient knowledge to avoid exposure to pathogens. The risk factors help you

Figure 12-8 Relationship between a diagnostic label and an etiology (related factor). **Source:** Redrawn from Hickey, P. (1990). *Nursing process handbook*. St. Louis, MO: Mosby.

► **TABLE 12-3**

Comparison of Interventions for Nursing Diagnoses with Different Etiologies

Nursing Diagnoses	Interventions
Client A	
Anxiety related to uncertainty over surgery	Provide detailed instructions about the surgical procedure, recovery process, and postoperative care activities
	Plan formal time for client to ask questions
Impaired physical mobility related to acute pain	Administer analgesics 30 minutes before planned exercise
	Instruct client in technique to splint painful site during activity
Client B	
Anxiety related to loss of job	Consult with social work to arrange for job consulting
	Encourage client to continue health promotion activities (e.g., exercise, routine social activities)
Impaired physical mobility related to musculoskeletal injury	Have client perform active range-of-motion exercises to affected extremity every 2 hours
	Instruct client on use of three-point crutch gait

► **TABLE 12-4** Defining Characteristics and Etiologies to Confirm Nursing Diagnoses

Assessment Activities	Defining Characteristics (Clustering Cues)	Nursing Diagnoses	Etiologies ("Related to")
Ask client to rate severity of pain on a scale from 0 to 10	Client verbally reports pain at a level of 8 or 9 when it becomes sharp	Acute pain	Physical pressure on spinal nerves
Observe client's positioning in bed	Client bends knees while on back to lessen pain		
Ask whether client has difficulty falling asleep or awakens during night from pain	Client reports feeling tired, awakens easily	Acute pain	Physical pressure on spinal nerves
Observe for any nonverbal signs of discomfort	Client moans and sighs when attempting to find comfortable position in bed		
Observe client's eye contact when client is talking	Client has poor eye contact when discussing surgery	Anxiety	Threat to health status as a result of surgery
Observe client's body language	Client is restless		
Ask client to describe feelings about surgery	Client is uncertain about what to expect after surgery and the outcome of surgery		
Give instruction in topic of interest, and return in 15 minutes to measure retention	Client forgets details of explanation	Anxiety	Threat to health status as a result of surgery

select the correct risk diagnosis, similar to the manner in which defining characteristics help you formulate actual nursing diagnoses. In addition, risk factors are valuable when you plan preventive nursing interventions.

Support of the Diagnostic Statement. Nursing assessment data must support the diagnostic label, and the related factors must be included in these data. To collect complete, relevant, and correct assessment data, it helps to identify assessment activities that produce specific kinds of data. For example, asking the client about the quality and perception of pain elicits subjective data. However, if palpating an area elicits a facial grimace, that grimace is objective information.

Likewise, asking a client to describe the perception of an irregular heartbeat elicits subjective information, and using auscultation to obtain a pulse elicits an objective measurement of heart rate and rhythm. When you review assessment data to look for clusters of defining characteristics, consider whether you have probed and assessed the client accurately and thoroughly to gather a complete database.

Concept Mapping for Nursing Diagnoses

When caring for a client or groups of clients, you need to think critically about client needs and how to prevent problems from

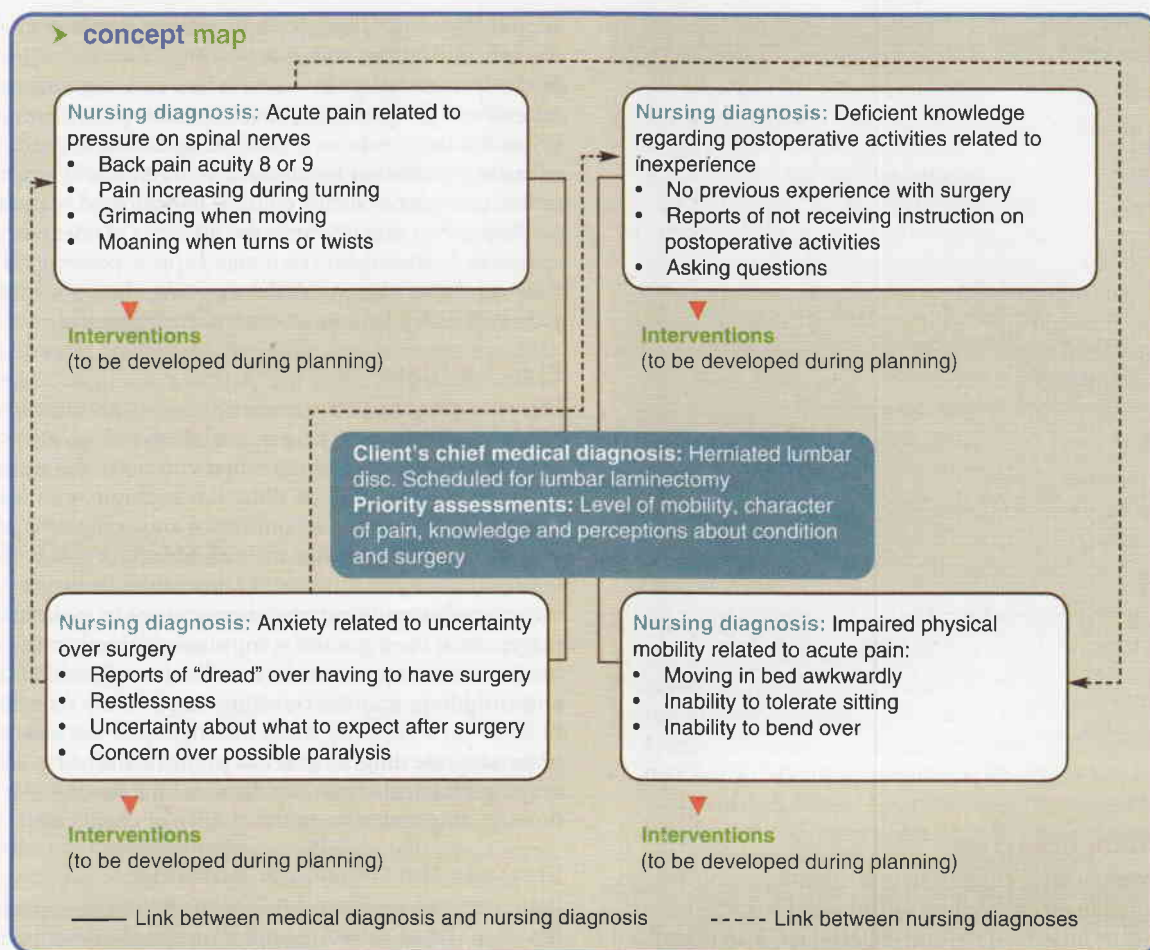

Figure 12-9 Concept map for Ms. Devine's nursing diagnoses.

developing. Concept mapping organizes and shows the interrelationship of client concerns to help you see the whole picture and not just limited parts (Pilcher, 2009). Concept mapping is one way to graphically represent the connections between concepts and ideas that are related to a central subject (e.g., the client's health problems).

Hsu and Hsieh (2005) describe a concept map as a scheme that displays visual knowledge in the form of a hierarchical graphic network. As you proceed in applying each step of the nursing process, your concept map expands with more detail about planned interventions.

Figure 12-9 shows the development of Lisa's concept map for Ms. Devine. Lisa began during the assessment step of the nursing process to gather a database for Ms. Devine. Her assessment included Ms. Devine's perspective of her health problems, as well as the objective and subjective data Lisa collected through observation and examination. Lisa validated findings and added to the database as she learned new information. Data sources include physical, psychological, and sociocultural domains.

Lisa applies clinical reasoning and intuition that reflects her own basic nursing knowledge, her past experiences with clients, patterns that she observed in similar situations, and reference to institutional standards and procedures (e.g., pain management policies or postoperative teaching protocols) (Ferrario, 2004). As Lisa begins to observe patterns of defining

characteristics, she places labels to identify the four nursing diagnoses that apply to Ms. Devine. She is also able to see the relationship between the diagnoses and connects them on the care map graphic. If Ms. Devine continues to be anxious, Lisa knows from her experience in caring for clients with pain that Ms. Devine's pain will increase. Likewise, increased pain will heighten anxiety. Anxiety also influences how well Ms. Devine will attend to any instructions, but until she understands what to expect, her anxiety will not diminish. Ms. Devine's pain, if unrelieved, will likely worsen her immobility.

The advantage of a concept map is its central focus on the client. It allows visualization of the "big picture" of the client's situation assisting the student to develop nursing care strategies that are individualized to the client and the client situation (Taylor & Wros, 2007). It promotes client participation with the eventual plan of care. Lisa's next step will be to collaborate with Ms. Devine to identify interventions appropriate for Ms. Devine's care and then add these to the concept map.

Sources of Diagnostic Errors

Errors occur in the nursing diagnostic process during data collection, interpretation and analysis, clustering, and in statement of the diagnosis. As a nurse, you need to apply methodical critical thinking so that the nursing diagnostic process is accurate.

► BOX 12-5 Sources of Diagnostic Error**Collecting**

Lack of knowledge or skill
Inaccurate data
Missing data
Disorganization

Interpreting

Inaccurate interpretation of cues
Failure to consider conflicting cues
Using an insufficient number of cues
Using unreliable or invalid cues
Failure to consider cultural influences or developmental stage

Clustering

Insufficient clustering of cues
Premature or early closure of clustering
Incorrect clustering

Labelling

Wrong diagnostic label selected
Existence of evidence that another diagnosis is more likely
Condition incorrectly overlooked as a collaborative problem
Failure to validate nursing diagnosis with client
Failure to seek guidance

Errors in Data Collection

To avoid errors in data collection, you should be knowledgeable and skilled in all assessment techniques (Box 12-5). Check for inaccurate or missing data, and collect data in an organized way. The following practice tips are essential to avoid data collection errors:

- Review your level of comfort and competence with interview and physical assessment skills before you begin data collection.
- Approach assessment in steps. Focus on completing a client interview before starting a physical examination. Perhaps focus on only one body system to learn how to gather a complete assessment. Then move to a more complex head-to-toe examination.
- Review your clinical assessments in clinical or classroom settings. They will provide you with a constructive learning opportunity to determine how to revise an assessment or to gather additional information.
- Determine the accuracy of your data. For example, when you auscultate abnormal lung sounds for the first time, be sure of what you hear through the stethoscope. To minimize the risk of inaccuracy, have a more experienced co-worker validate your findings or explain why they are incorrect. Validate your assessment data by double-checking and verifying.
- Be organized in any examination. Have the appropriate forms and examination equipment ready to use. Be sure the environment is private, quiet, and comfortable for the client.

Errors in Interpretation and Analysis of Data

After data collection, review your database to decide whether it is accurate and complete. Review data to confirm that measurable, objective physical findings support subjective data. For example, when a client reports “difficulty breathing,” you

should listen to lung sounds, assess respiratory rate and oxygen saturation, and measure the client’s chest excursion. Begin interpretation by identifying and organizing relevant assessment patterns to confirm the presence of client problems. Be careful to consider any conflicting cues or to decide whether cues are insufficient for forming a diagnosis. It is very important to consider a client’s cultural background or developmental stage when you interpret the meaning of cues. For example, clients from the Middle East may express pain very differently than do Asian clients. Misinterpreting clients’ expressions of pain will easily lead to an inaccurate diagnosis.

Errors in Data Clustering

Errors in data clustering occur when data are clustered prematurely or incorrectly or are not clustered at all. Premature closure of clustering occurs when you make the nursing diagnosis before grouping all data. For example, you learn that a client has had urinary incontinence and complains of urgency and nocturia. You cluster the available data and consider that *impaired urinary elimination* is a probable diagnosis. However, incorrect clustering occurs when you try to make the nursing diagnosis fit the signs and symptoms obtained. In this example, further assessment reveals the client has bladder distension and dribbling, and the condition is probably overflow incontinence. As a result of these findings, you are able to make a more accurate diagnosis: *urinary retention*. Always identify the nursing diagnosis from the data, not the reverse. An incorrect nursing diagnosis affects the quality of client care.

Errors in the Diagnostic Statement

Inaccurately interpreting the nursing diagnosis may result in developing and delivering inappropriate interventions leading to undesirable outcomes (Lunney, 2009). To reduce errors, word the diagnostic statement in appropriate, concise, and precise language. Use correct terminology reflecting the client’s response to the illness or condition. Use of standardized nursing language from NANDA International (2009) helps ensure accuracy. A diagnostic statement such as “unhappy and worried about health” is not a scientifically based diagnosis, and it will lead to errors. The language needs to be more precise and appropriate, such as *ineffective coping related to fear of medical diagnosis*. The problem and etiological portions of the diagnostic statement need to be within the scope of nursing in order to be diagnosed and treated.

Documentation

Once you identify a client’s nursing diagnoses, list them on the written plan of care. In the clinical facility, list nursing diagnoses chronologically as you identify them. When you initiate the original care plan, always list the highest priority nursing diagnoses first.

Thereafter, add additional nursing diagnoses to the list. Date a nursing diagnosis at the time of entry. When you care for a client, review the list and identify the nursing diagnoses with the highest priority, regardless of chronological order.

Nursing Diagnoses: Application to Care Planning

Nursing diagnosis is a mechanism for identifying the nursing care necessary for clients. Diagnoses provide direction for the planning process and the selection of nursing interventions to achieve desired outcomes for clients. Just as the medical

diagnosis of diabetes guides a physician to prescribe a low-carbohydrate diet and medication for blood glucose control, the nursing diagnosis of *impaired skin integrity* directs a nurse to apply certain support surfaces to a client's bed and to initiate a turning schedule. In Chapter 13, you learn how unifying the language of NANDA International, along with the Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC), facilitates the process of matching nursing diagnoses with accurate and appropriate interventions and outcomes (Dochterman & Jones, 2003). The care plan is a map for nursing care and demonstrates your accountability for client care. By learning to make accurate nursing diagnoses, your subsequent care plan will assist in communicating to other professionals the client's health care problems and ensure that you select relevant and appropriate nursing interventions.

❖ KEY CONCEPTS

- The nursing process employs critical thinking to identify, diagnose, and treat clients' responses to health and illness.
- Nursing assessment involves the collection and verification of data and the analysis of all data to establish a database about a client's perceived needs, health problems, and responses to those problems.
- By interpreting the meaning of cues, you form an inference, which then enables you to identify meaningful clusters of information.
- To conduct a comprehensive assessment, you use a structured database format or a problem-oriented approach.
- The interview is an organized conversation with a client that begins by establishing a therapeutic relationship with the client and that aids in the investigation and discussion of the client's health care needs.
- Open-ended questions encourage clients to describe their health histories in detail, whereas closed-ended questions present a list of possible choices for the client.
- An interview includes three phases: orientation, working, and termination.
- Once a client provides subjective data, you consider exploring the findings further by collecting objective data.
- During assessment, you critically anticipate and use an appropriate branching set of questions or observations to collect data, and cues of assessment information are clustered to identify emerging patterns and problems.
- Written data statements are descriptive, to the point, and complete and do not include inferences or interpretative statements.
- Family members and friends sometimes offer observations about the client's needs; these observations will affect the way you deliver care.
- During assessment, you encourage clients to describe their histories of illnesses or health care problems.
- To form a nursing judgement, you critically assess a client, validate the data, interpret the information gathered, and look for diagnostic cues that will lead you to identify the client's problems.
- NANDA International has developed a common language that enables all members of the health care team to understand a client's needs.
- The analysis and interpretation of data require you to validate data, recognize patterns or trends, compare data with healthful standards, and then form diagnostic conclusions.

- The absence of defining characteristics suggests that you reject a proposed diagnosis.
- Three types of nursing diagnoses exist: actual, at risk, and wellness diagnoses.
- A nursing diagnosis is written in a two-part format, including a diagnostic label and an etiological or related factor.
- The "related to" factor of the diagnostic statement assists you in individualizing a client's nursing diagnoses and provides direction for your selection of appropriate interventions.
- Risk factors serve as cues to indicate that a risk nursing diagnosis applies to a client's condition.
- Concept mapping is a visual representation of a client's nursing diagnoses and their relationship with one another.
- Nursing diagnostic errors occur through errors in data collection, in interpretation and analysis of data, in clustering of data, or in the diagnostic statement.
- Nursing diagnoses improve communication between nurses and other health providers.

❖ CRITICAL THINKING EXERCISES

1. Mrs. Lewis comes to the well-baby clinic for her infant's one-month examination. She tells her nurse, Ethan, that the baby has not been sleeping well during the night. In addition, Mrs. Lewis has noted a rash on the baby's abdomen. Write three questions that Ethan might ask to assess the two potential problems Mrs. Lewis has presented. What assessment technique might the nurse apply to assess the rash that would not be used to assess the baby's sleep pattern?
2. Mrs. Spezio has a pressure ulcer over the coccyx that is 5 cm in diameter and approximately 1 cm deep. The tissue surrounding the ulcer is inflamed and tender to touch. Mrs. Spezio is transferring from a long-term care facility where she had resided for six months after a massive stroke. She is unable to move independently in bed and does not sense pressure or discomfort over her coccyx or hips. In view of this clinical situation, identify the defining characteristics and related factors for the nursing diagnosis *impaired skin integrity*.

❖ REVIEW QUESTIONS

1. The purpose of assessment is to
 1. Make a diagnostic conclusion
 2. Delegate nursing responsibility
 3. Teach the client about his or her health
 4. Establish a database concerning the client
2. The nurse completes a nursing health history with her client. In order to avoid incorrect inferences and ensure the data are accurate, the nurse's next step is to
 1. Analyze and interpret the data
 2. Document the data
 3. Validate data with the client
 4. Share the data with other health care providers
3. During data clustering, a nurse
 1. Provides documentation of nursing care
 2. Reviews data with other health care providers
 3. Makes inferences about patterns of information
 4. Organizes cues into patterns that enable the nurse to identify nursing diagnoses

4. You gather the following assessment data. Which of the following cues form a pattern? (Choose all that apply.)
 1. The client is restless.
 2. Fluid intake for 8 hours is 800 mL.
 3. The client complains of feeling short of breath.
 4. The client has drainage from surgical wound.
 5. Respirations are 24 per minute and irregular.
 6. Client reports loss of appetite for more than two weeks.
5. A nursing diagnosis is
 1. The diagnosis and treatment of human responses to health and illness
 2. The advancement of the development, testing, and refinement of a common nursing language
 3. A clinical judgement about individual, family, or community responses to actual and potential health problems or life processes
 4. The identification of a disease condition on the basis of a specific evaluation of physical signs, symptoms, the client's medical history, and the results of diagnostic tests
6. Lisa reviews data that she has collected regarding Ms. Devine's pain symptoms. She compares the defining characteristics for *acute pain* with those for *chronic pain*. In the end, she selects *acute pain* as the correct diagnosis. This is an example of how Lisa avoids an error in
 1. Data collection
 2. Data clustering
 3. Data interpretation
 4. Making a diagnostic statement
7. One of the purposes of the use of standard formal nursing diagnostic statements is to
 1. Evaluate nursing care
 2. Gather information on client data
 3. Help nurses to focus on the role of nursing in client care
 4. Facilitate understanding of client problems among health care providers
8. The nursing diagnosis *readiness for enhanced communication* is an example of
 1. A risk nursing diagnosis
 2. An actual nursing diagnosis
 3. A potential nursing diagnosis
 4. A wellness nursing diagnosis
9. The nursing diagnosis *hypothermia* is an example of
 1. A risk nursing diagnosis
 2. An actual nursing diagnosis
 3. A potential nursing diagnosis
 4. A wellness nursing diagnosis
10. The word *impaired* in the diagnosis *impaired physical mobility* is an example of a
 1. Descriptor
 2. Risk factor
 3. Related factor
 4. Nursing diagnosis
11. Nurses use a variety of assessment techniques for data collection. The nurse knows that the first appropriate assessment technique for data collection is
 1. Review client's medical record
 2. Interview client
 3. Consult health care team
 4. Review literature
12. Casey is reviewing a client's list of nursing diagnoses in the medical record. The most recent nursing diagnosis is *diarrhea related to intestinal colitis*. This is an incorrectly stated diagnostic statement, best described as
 1. Identifying the clinical sign instead of an etiology
 2. Identifying a diagnosis on the basis of prejudicial judgement
 3. Identifying the diagnostic study rather than a problem caused by the diagnostic study
 4. Identifying the medical diagnosis instead of the client's response to the diagnosis
13. Which of the following are defining characteristics for the nursing diagnosis *impaired urinary elimination*? (Choose all that apply.)
 1. Nocturia
 2. Frequency
 3. Urine retention
 4. Inadequate urinary output
 5. Treatment with intravenous fluids
 6. Sensation of bladder fullness

Planning and Implementing Nursing Care

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by Willena I. Nemeth, RN, MN, S. Helen Fraser, RN, MN, and Debbie A. Brennick, RN, MN

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Explain the relationship between planning and nursing assessment and diagnosis.
- Discuss the criteria used in priority setting.
- Describe goal setting.
- Discuss the difference between a goal and an expected outcome.
- List the seven guidelines for writing an outcome statement.
- Develop a plan of care from a nursing assessment.
- Discuss the differences between nurse-initiated, physician-initiated, and collaborative interventions.
- Discuss the process of selecting nursing interventions.
- Describe the purposes of a written nursing care plan.
- Describe the elements of a concept map.
- Describe the consultation process.
- Explain the relationship of implementation to the nursing diagnostic process.
- Discuss the differences between protocols and medical directives or standing orders.
- Describe the association between critical thinking and selecting nursing interventions.
- Identify preparatory activities to perform before implementation.
- Discuss steps taken to revise a plan of care before performing implementation.
- Define the three implementation skills.
- Describe and compare direct and indirect nursing interventions.
- Select appropriate interventions for an assigned client.

key terms

Planning Nursing Care

Lisa is beginning to plan the nursing care for Ms. Devine. In the diagnostic step of the nursing process (see Chapter 12), Lisa identified four nursing diagnoses relevant to Ms. Devine's case: acute pain, anxiety, deficient knowledge, and impaired physical mobility. Lisa is responsible for planning Ms. Devine's care from this morning until the time Ms. Devine leaves for surgery. Lisa will have left work on the unit by the time Ms. Devine returns from surgery, but as her primary nurse, Lisa will provide direction for the staff who assume Ms. Devine's care. Careful planning involves seeing a relationship between a client's problems, recognizing that certain problems take precedence over others, and proceeding with a safe and efficient approach to care. For each of the diagnoses, Lisa identifies the goals and expected outcomes that she and the client hope to achieve. The goals and outcomes direct Lisa in selecting appropriate therapeutic interventions suited to Ms. Devine's own needs, strengths, and limitations. Lisa knows she needs to develop a plan quickly, because Ms. Devine is to go to the operating room by noontime.

Figure 13-1 A model for priority setting. **Source:** Adapted from Hendry, C., & Walker, A. (2004). Priority setting in clinical nursing practice. *Journal of Advanced Nursing*, 47, 427–436.

After you identify a client's nursing diagnoses and strengths, you begin planning nursing care. **Planning** is a category of nursing behaviour in which a nurse sets client-centred goals, outlines expected outcomes, plans nursing interventions, and selects interventions that will resolve the client's problems and achieve the goals and outcomes. Planning requires critical thinking, applied through deliberate decision making and problem solving to set priorities for a client. Many clients have multiple diagnoses and a number of health problems. Successful planning requires that you collaborate with the client and family, consult with other members of the health care team, and review related literature. This literature includes available evidence related to the client's health problems. A plan of care is dynamic and will change as you meet the client's needs or identify new needs.

Establishing Priorities

Priority setting is the ranking of nursing diagnoses or client problems, through the use of principles such as urgency or importance, to establish a preferential order for nursing actions (Hendry & Walker, 2004; Figure 13-1). By ranking nursing diagnoses in order of importance, you attend to the client's most important needs first. Priorities help you to anticipate and sequence nursing interventions for a client who has multiple nursing diagnoses and health problems. When feasible, you and your clients select mutually agreed-upon priorities on the bases of the urgency of the problems, safety, the nature of the treatment indicated, and the relationship among the diagnoses.

Establishing priorities or determining urgency of the identified health problems is done on the basis of their severity or physiological importance (Lewis et al, 2010). Nursing diagnoses of conditions that, if untreated, result in harm to the client or others have the highest priorities. For example, *risk for other directed violence*, *impaired gas exchange*, and *decreased cardiac output* are typically high-priority nursing diagnoses that raise

issues of safety, adequate oxygenation, and adequate circulation. High priorities are sometimes both physiological and psychological and may address other basic human needs. Consider Ms. Devine's case. Among Ms. Devine's nursing diagnoses, *acute pain* and *anxiety* are of the highest priority. Lisa knows that she needs to relieve Ms. Devine's acute pain and lessen the client's anxiety so that the client will approach surgery in less distress.

Intermediate priority nursing diagnoses involve the none-emergency, non-life-threatening needs of the client. In Ms. Devine's case, *deficient knowledge* is an intermediate diagnosis. It is very important that Lisa properly prepare Ms. Devine for surgery. Focused and individualized instruction will help Ms. Devine understand what to expect during her preoperative preparation and how to participate in postoperative care activities. Attending to the diagnosis of *deficient knowledge* will help minimize postoperative complications. Once Lisa addresses the higher priority nursing diagnoses of pain and anxiety, Ms. Devine will probably be more able to learn postoperative care. Also, greater understanding of the surgical procedure may help relieve Ms. Devine's anxiety.

Low-priority nursing diagnoses are not always directly related to a specific illness or prognosis but affect the client's future well-being. Many low-priority diagnoses focus on the client's long-term health care needs. In Ms. Devine's situation, *impaired physical mobility* is caused in part by her pain but also by her medical condition: a herniated disc. Lisa will monitor this diagnosis carefully, especially postoperatively. For now, Lisa will administer prescribed pain medication to make Ms. Devine as comfortable as possible, which may improve Ms. Devine's ability to turn and position herself. After the surgery, Lisa will reassess her client. If *impaired physical mobility* remains a problem, the diagnosis is a higher priority because it is essential for Ms. Devine to achieve more normal mobility for a full recovery and to prevent postoperative complications.

The order of priorities changes as a client's condition changes, sometimes within a matter of minutes. Ongoing client assessment is essential for determining the priority of your client's nursing diagnoses.

In considering time as a factor in setting priorities, White (2003) explained that the planning of nursing care occurs in three phases: initial, ongoing, and discharge. Initial planning involves development of a preliminary plan of care after admission assessment and initial selection of nursing diagnoses. Because of progressively shorter lengths of hospitalization, initial planning is important in addressing nursing diagnoses and collaborative problems in order to hasten problem resolution. Ongoing planning involves continuous updating of the client's plan of care. As the client's condition changes, you assess new information about the client and evaluate the client's status. Discharge planning involves the anticipation and preparation for meeting the client's needs after discharge. This is a vital phase of planning that should begin upon admission or when care begins. It continues throughout the period of care.

Lisa is now involved with the initial planning of Ms. Devine's care. Lisa needs to initiate interventions to manage each of Ms. Devine's nursing diagnoses before surgery. Once Ms. Devine returns from the operating room, Lisa, or another nurse, will conduct ongoing planning by further assessing Ms. Devine's status and then redefining nursing diagnoses that apply postoperatively. As Ms. Devine recovers from surgery, Lisa and her colleagues will work together in developing

a discharge plan that will assist Ms. Devine in returning home in as healthy a condition as possible.

As a nurse, you need to prioritize the specific interventions or strategies that you will use to help a client achieve desired goals and outcomes. For example, as Lisa considers the high-priority diagnosis of *acute pain* for Ms. Devine, she decides which intervention, among the interventions of administering an analgesic, repositioning, and teaching relaxation exercises, to perform first. Lisa knows that a certain degree of pain relief is necessary before a client can attend to relaxation exercises. She may decide to turn and reposition Ms. Devine and then give her an analgesic. However, if Ms. Devine is too uncomfortable to turn, Lisa will select administering the analgesic as her first priority. It is important to involve the client in priority setting whenever possible; in some situations, you and your client have different priorities.

Critical Thinking in Establishing Goals and Expected Outcomes

Once you identify a nursing diagnosis, you must identify the best approach to address and resolve the problem. What do you plan to achieve? **Goals and expected outcomes** are specific client behaviour or physiological responses that you set to achieve through nursing diagnosis or collaborative problem resolution. They provide a clear focus for the type of interventions necessary to care for your client.

For example, in the case of Ms. Devine, who has a diagnosis of *acute pain related to pressure on spinal nerves*, a goal of care includes “Client achieves improved pain control before surgery.” To monitor Ms. Devine’s progress, Lisa must use expected outcomes or measurable criteria to evaluate goal achievement. Measurable outcomes for the goal of pain relief include “Client’s self-report of pain will be 3 or less on a scale of 0 to 10,” and “Client will be able to turn without additional discomfort.” The outcomes will reflect Lisa’s success in selecting interventions for Ms. Devine’s pain relief. After administering an analgesic and repositioning the client, Lisa will return to Ms. Devine’s room in 30 minutes and ask her to rate her pain and comfort level. If Ms. Devine rates her pain at a 3 or less and similarly reports no additional discomfort when turning, her goals will have been met. Lisa will follow her plan until Ms. Devine goes to the operating room. Goals and expected outcomes serve two purposes: to provide clear direction for the selection and use of nursing interventions and to provide focus for evaluating the effectiveness of the interventions.

Planning nursing care requires critical thinking (Figure 13-2). You need to carefully evaluate the identified nursing diagnoses, the urgency of the problems, and the resources of the client and the health care delivery system. You apply knowledge from the nursing, medical, and sociobehavioural sciences to plan client care. To select goals, expected outcomes, and interventions, you must consider your previous experience with similar client problems, as well as any established standards for nursing practice. Goals and outcomes need to be

Figure 13-2 Critical thinking and the process of planning care. CNA, Canadian Nurses Association.

relevant to client needs and to be specific, observable, measurable, time-limited, and achievable.

For example, in choosing a plan for managing the client's acute pain, Lisa creatively selects a comfort measure that Ms. Devine practises at home. The diagram in Figure 13-3 graphically illustrates the relationships between nursing diagnoses, goals, expected outcomes, and nursing interventions.

Goals of Care

A **client-centered goal** is a specific and measurable behavioural response that reflects a client's highest possible level of wellness and independence in function. Examples are "Client will perform self-care hygiene independently" and "client will remain free of infection." A goal is realistic and based on client

needs and resources. A client goal represents predicted resolution of a nursing diagnosis or health problem, proof of progress toward resolution, enhanced improved health status, or continued maintenance of optimal health (Carpenito-Moyet, 2008). A goal involves only one behaviour or response. The example of "Client will administer a self-injection and demonstrate infection control measures" is incorrect because the statement includes two different behaviours: "administer" and "demonstrate." Instead, the goal should be worded as follows: "Client will administer a self-injection." The specific criteria you use to measure success of the goal are the expected outcomes: for example, "Client will prepare medication dose correctly" and "Client uses aseptic technique when preparing injection site." Each goal is time-limited so that the health care team has a common time frame for problem resolution. The time frame depends on the nature of the problem, etiology, overall condition of the client, and treatment setting.

A **short-term goal** is an objective behaviour or response that you expect a client to achieve in a short time, usually less than a week. In an acute care setting, you set goals for over a course of just a few hours. Such was the case when Lisa set for Ms. Devine the goal "Client's level of comfort will improve before surgery." A **long-term goal** is an objective behaviour or response that you expect a client to achieve over a longer period, usually over several days, weeks, or months: for example, "Client will be tobacco-free within 60 days." Goal setting establishes the framework for the nursing care plan. Table 13-1 outlines the progression from nursing diagnoses to goals and expected outcomes, which Lisa individualizes to meet Ms. Devine's needs.

Role of the Client in Goal Setting. It is important to work closely with clients in setting goals. Mutual goal setting is an activity that includes clients and families in prioritizing goals of care and in developing plans for action (Bulechek et al., 2008). Clients need to be able to engage in problem solving and decision making in order to participate effectively in goal setting. Goals that are determined with the client, and have a clear action plan, are more likely to be successful. For example, Lisa and Ms. Devine set the goal "Client will report greater comfort." They agreed that this would be demonstrated by pain acuity rated less than 3 on a scale of 0 to 10, a level that Ms. Devine reports is tolerable for her.

Figure 13-3 From diagnosis to outcome. **Source:** Revised and redrawn from Gordon, M. (1994). *Nursing diagnosis: Process and application* (3rd ed.). St Louis, MO: Mosby.

TABLE 13-1 Examples of Goal Setting with Expected Outcomes for Ms. Devine

Nursing Diagnoses	Goals	Expected Outcomes
Acute pain related to pressure on spinal nerves	Ms. Devine's level of comfort will improve before surgery.	Client will be able to turn without reported discomfort in two hours. Client's self-report of pain will be 3 or less on a scale of 0 to 10 by the time of scheduled surgery.
Anxiety related to uncertainty over surgery	Ms. Devine will accept plan for surgical care before scheduled surgery.	Client will express less uneasiness about surgical experience in next four hours.
Deficient knowledge regarding postoperative activities related to inexperience	Ms. Devine will understand treatment procedures planned postoperatively within four hours.	Client will describe purpose of postoperative exercises prior to scheduled surgery. Client will demonstrate use of incentive spirometer and deep breathing and coughing prior to scheduled surgery. Client will explain purpose of postoperative nursing care prior to scheduled surgery.
Impaired physical mobility related to acute back pain	Ms. Devine will move independently in bed before surgery.	Client will initiate turning without additional discomfort within two hours. Client will position self for care procedures within two hours.

Expected Outcomes

An expected outcome is a specific measurable change in a client's status that you expect in response to nursing care. Expected outcomes provide a focus or direction for nursing care because they are the desired physiological, psychological, social, developmental, or spiritual responses that indicate resolution of clients' health problems. Derived from both short- and long-term goals, outcomes determine when a specific client-centred goal has been met.

Usually you list several expected outcomes for each nursing diagnosis and goal. The reason for the multiple expected outcomes is that sometimes one nursing action is not enough to resolve a specific problem. In addition, the listing of the step-by-step expected outcomes assists in planning interventions. Write expected outcomes sequentially, specifying time frames for each (see Table 13-1). Time frames provide progressive steps to recovery and assist in ranking nursing interventions. In addition, time frames set limits for problem resolution. In the case of Ms. Devine, Lisa plans to reduce her pain to a level less than 3 so she is able to turn comfortably in bed within the next two hours.

Write expected outcome statements in measurable terms. This enables you to note the specific behaviour or physiological response expected for resolution of the problem. For example, "Client will have less pain" is an inaccurate outcome statement because the phrase "less pain" is nonspecific. The statement "Client will report pain acuity of less than 3 on a scale of 0 to 10" is accurate.

Nursing Outcomes Classification. The current health care environment pays considerable attention to measuring outcomes sensitive to nursing interventions. Many health care administrators focus on outcomes in determining staffing and other resources in health care settings. The Iowa Intervention Project published the Nursing Outcomes Classification (NOC) and has linked the outcomes to NANDA International (2009) nursing diagnoses (University of Iowa College of Nursing, 2008). The Iowa researchers defined a **nursing-sensitive client outcome** as an individual, family, or community behaviour or perception that is measurable along a continuum in response to a nursing intervention. For any given NANDA International nursing diagnosis, multiple outcomes are suggested in NOC. These outcomes provide descriptions of the focus of nursing care and include indicators for measuring success with interventions (Table 13-2).

Combining Goals and Outcome Statements

Nurses within health care settings may refer to the terms, goals, and outcomes interchangeably. This is acceptable as long as the criteria for writing goals and outcomes are met. For example, the statement "Client will achieve pain control as evidenced by reporting pain acuity of less than 3 on a scale of 0 to 10 within 24 hours" is an acceptable statement. The goal portion of the statement broadly describes the desired client status ("achieve pain control"), and the outcome portion of the statement contains the observable criterion ("3 on a [pain] scale") needed to measure success.

Guidelines for Writing Goals and Expected Outcomes

There are seven guidelines for writing goals and expected outcomes: client-centred, singular, observable, measurable, time-limited, mutual, and realistic.

► TABLE 13-2

Examples of NANDA International Nursing Diagnoses and Suggested NOC Linkages

Nursing Diagnosis	Suggested NOC-Based Outcomes (Examples)	Outcome Indicators (Examples)
Deficient knowledge	Knowledge: treatment procedures	Description of treatment procedure Description of steps in procedure
	Client satisfaction: teaching	Explanations provided in understandable terms Explanation of activity restrictions
Activity intolerance	Activity tolerance	Oxygen saturation with activity Pulse rate with activity Respiratory rate with activity
	Self-care status	Bathes self Dresses self Prepares food and fluid for eating

Client Goal or Outcome. Outcomes and goals reflect client responses that are expected after nursing interventions. Write a goal to reflect client behaviour, not to reflect your goals or interventions. A correct outcome statement is "Client will ambulate in the hall three times a day." A common error is to write "Ambulate client in the hall three times a day."

Singular Goal or Outcome. Be precise in evaluating a client response to a nursing action. Each goal and outcome addresses only one behaviour or response.

Observable Goal or Outcome. You need to be able to observe whether change in a client's status occurs. Changes in physiological findings and in the client's knowledge, perceptions, and behaviour are observable. You observe outcomes by directly asking clients about their condition and by using assessment skills. For the outcome "Chest sounds will be clear on auscultation by 8/31," you auscultate the client's chest routinely after therapy (e.g., inhalation, percussion). The outcome statement "Client will appear less anxious" is not a correct statement because no specific behaviour for "will appear" is observable.

Measurable Goal or Outcome. You will learn to write goals and expected outcomes that set standards against which to measure the client's response to nursing care. Examples such as "Body temperature will remain between the normal range of 36.5–37.5° C" and "Apical pulse will remain between 60 and 100 beats per minute" enable you to objectively measure changes in the client's status.

Time-Limited Goal or Outcome. The time frame for each goal and expected outcome indicates when you expect the response to occur. Time frames assist in determining progress toward goals and outcomes.

Mutual Goal or Outcomes. Mutually set goals and expected outcomes ensure that client and nurse agree on the direction and time limits of care. Mutual goal setting increases clients' motivation and cooperation.

Realistic Goal or Outcome. Set goals and expected outcomes that are achievable. This provides clients with a sense of empowerment that increases motivation and cooperation. In order to establish realistic goals, you need to assess the resources of the client, the family, the health care facility, and the community. You need to be aware of the client's physiological, emotional, cognitive, and sociocultural influences and take into consideration the client's determinants of health.

Types of Interventions

Nursing interventions belong to three categories: nurse-initiated, physician-initiated, and collaborative. Interventions are based on client needs. Some clients require all three categories of interventions, whereas others need only nurse- and physician-initiated interventions.

Nurse-initiated interventions are **independent nursing interventions**. These do not require direction or orders from other health care providers. As a nurse, you act independently for clients. Nurses' actions are grounded in evidence-informed decision making. Examples include elevating an edematous extremity, instructing clients about side effects of medications, or directing a client how to splint an incision during coughing.

Physician-initiated interventions are **dependent nursing interventions**, or actions that require orders or directions from physicians. The interventions are directed toward treating or managing a medical diagnosis. Nurse practitioners working under collaborative agreements with physicians or who are licensed through provincial or territorial nursing legislation are also able to provide such orders or directions for care. As the nurse, you intervene by carrying out these written orders or verbal orders in the case of emergency situations. Administering a medication and changing a dressing are examples of written physician-initiated interventions.

Each physician-initiated intervention requires specific nursing responsibilities that are based on nursing knowledge. For example, when administering medications, you are responsible for knowing the classification of the drug, its physiological action, the normal dosage, side effects, and nursing interventions related to its action or side effects (see Chapter 33).

Interdependent nursing interventions, or **collaborative interventions**, are therapies that require the combined knowledge, skill, and expertise of a number of health care providers. Typically, when you plan care for a client, you review the necessary interventions and determine whether the collaboration is necessary. An interdisciplinary health care team conference about a client's care is useful in determining interdependent nursing interventions.

In the case study involving Lisa and Ms. Devine, Lisa will initiate independent nursing interventions to help calm Ms. Devine's anxiety and to begin teaching her about postoperative care. Lisa will independently assist Ms. Devine to change position in bed to minimize her discomfort and promote increased mobility. The dependent interventions Lisa plans to implement are administering an analgesic and completing any necessary preoperative diagnostic tests. Lisa decides that consultation with the unit social worker is another way to help Ms. Devine with her anxiety over surgery; this is an example of a collaborative intervention. A nurse is required to have the appropriate and specific knowledge base, skills, and abilities, that are evidence based, to be able to recognize and

► TABLE 13-3

Frequent Errors in Writing Nursing Interventions

Type of Error	Incorrectly Stated Nursing Intervention	Correctly Stated Nursing Intervention
Failure to precisely or completely indicate nursing actions	Turn client every two hours	Turn client every two hours, using the following schedule: 0800: supine 1000: left side 1200: prone 1400: right side (repeat this routine beginning at 1600 and 2400)
Failure to indicate frequency	Perform blood glucose measurements	Measure blood glucose before each meal: 0700, 1100, and 1600
Failure to indicate quantity	Irrigate wound once a shift: 0800, 1600, and 2400	Irrigate wound with 100 mL normal saline until clear: 0800, 1600, and 2400
Failure to indicate method	Change client's dressing once a shift: 0800, 1600, and 2400	Replace client's dressing with Neosporin ointment to wound and two dry 4x4 dressings secured with hypoallergenic tape, once a shift: 0800, 1600, and 2400

question errors to competently care for assigned client populations (Table 13-3). The ability to recognize incorrect orders or therapies is the responsibility of the nurse before implementation of any order or therapy. Errors may occur in writing or transcribing orders. Clarifying an order is competent nursing practice and protects clients from harm. When you carry out an incorrect or inappropriate intervention, you are responsible for an error in judgement and are legally responsible for any complications resulting from the error (see Chapter 8).

Selection of Interventions

Interventions are not selected randomly. Clients with the diagnosis of *anxiety*, for example, may require a variety of interventions. You treat anxiety related to the uncertainty of impending surgery very differently than anxiety related to a possible loss of family role function. When choosing interventions, consider six factors: (1) the nursing diagnosis, (2) goals and expected outcomes, (3) the evidence base (e.g., research or proven practice guidelines), (4) feasibility, (5) acceptability to the client, and (6) your own competence (Bulechek et al., 2008)

► BOX 13-1 Choosing Nursing Interventions

Characteristics of the Nursing Diagnosis

Interventions should alter the etiological ("related to") factor or signs and symptoms associated with the diagnostic label.

- When an etiological factor cannot change, direct the interventions toward treating the signs and symptoms (e.g., NANDA International [2009] defining characteristics).
- For potential or high-risk diagnoses, direct interventions at altering or eliminating risk factors for the diagnosis.

Expected Outcomes

Because nurses state outcomes in terms used to evaluate the effect of an intervention, this language assists in selecting the intervention. NIC is designed to show the link to NOC (University of Iowa College of Nursing, 2008).

Evidence Base

Research evidence in support of a nursing intervention indicates the effectiveness of the intervention in certain types of clients.

- Refer to the evidence (e.g., research articles, evidence-informed decision making, or evidence-informed nursing practice protocols that describe the use of the evidence in similar clinical situations and settings).
- When research is not available, use scientific principles (e.g., infection control) or consult a clinical expert about your client population.

Feasibility

A specific intervention has the potential for interacting with other interventions.

- Be knowledgeable about the total plan of care.
- Consider cost: Is the intervention clinically effective and cost efficient?
- Consider time: Are time and personnel resources available?

Acceptability to the Client

A treatment plan needs to be acceptable to the client and/or family and must match the client's goals, health care values, and culture.

- Promote informed choice; help a client know how to participate in and anticipate the effect of interventions.

Capability of the Nurse

The nurse needs to have current knowledge of the intervention, its scientific basis, and considerations for implementation.

- Be prepared to carry out the intervention.
- Know the **scientific rationale** for the intervention.
- Have the necessary psychosocial and psychomotor skills to complete the intervention.
- Be able to function within the specific setting and to use health care resources effectively and efficiently.

Adapted from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St Louis, MO: Mosby.

(Box 13-1). During deliberation, review resources such as the nursing literature, standard protocols or guidelines, the Nursing Interventions Classification (NIC), critical pathways, policy or procedure manuals, and textbooks. Collaborate with other professionals, review your clients' needs and priorities, and review your previous experiences to select interventions that have the best potential for achieving the expected outcomes.

► BOX 13-3 Example of Interventions and Associated Nursing Activities

Class: Physical Comfort Promotion Intervention-Environmental Management

Examples of Activities

- Create a safe environment for client
- Provide a clean, comfortable bed and environment
- Avoid unnecessary exposure, drafts, overheating, or chilling
- Provide music of choice
- Limit visitors
- Manipulate lighting for therapeutic benefit
- Bring familiar objects from home
- Allow family/significant other to stay with client

From Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St Louis, MO: Mosby.

Nursing Interventions Classification

The Iowa Intervention Project (1993) developed a set of nursing interventions that provides a level of standardization, which enhances communication of nursing care across all health care settings and enables health care professionals to compare outcomes (Bulechek et al., 2008). The NIC model has three levels: domains, classes, and interventions for ease of use. The domains are the highest level (Level 1) of the model, worded in broad terms (e.g., "safety" and "physiological: basic") to organize the more specific classes and interventions (Table 13-4). The second level of the model includes 30 classes, which offer useful clinical categories for reference in selecting interventions. The third level of the model includes the 514 interventions, defined as any treatment based on clinical judgement and knowledge, that a nurse performs to enhance the condition of a client who presents an alteration within the class (Bulechek et al., 2008) (Box 13-2). Each intervention can be performed with a variety of nursing activities (Box 13-3). Nursing activities are those commonly used in a plan of care. NIC-based interventions are also linked with NANDA

► TABLE 13-4 Nursing Interventions Classification (NIC) Taxonomy

Domain 1	Domain 2	Domain 3	Domain 4	Domain 5	Domain 6	Domain 7
Level 1 Domains						
1. Physiological: Basic Care that supports physical functioning	2. Physiological: Complex Care that supports homeostatic regulation	3. Behavioural Care that supports psychosocial functioning and facilitates lifestyle changes	4. Safety Care that supports protection against harm	5. Family Care that supports the family	6. Health System Care that supports effective use of the health care delivery system	7. Community Care that supports the health of the community
Level 2 Classes						
A. <i>Activity and Exercise Management:</i> Interventions to organize or assist with physical activity and energy conservation and expenditure	G. <i>Electrolyte and Acid-Base Management:</i> Interventions to regulate electrolyte/acid-base balance and prevent complications	O. <i>Behaviour Therapy:</i> Interventions to reinforce or promote desirable behaviours or alter undesirable behaviours	U. <i>Crisis Management:</i> Interventions to provide immediate short-term help in both psychological and physiological crises	W. <i>Childbearing Care:</i> Interventions to assist in understanding and coping with the psychological and physiological changes during the childbearing period	Y. <i>Health System Mediation:</i> Interventions to facilitate the interface between client/family and the health care system	c. <i>Community Health Promotion:</i> Interventions that promote the health of the whole community
B. <i>Elimination Management:</i> Interventions to establish and maintain regular bowel and urinary elimination patterns and manage complications due to altered patterns	H. <i>Drug Management:</i> Interventions to facilitate desired effects of pharmacological agents	P. <i>Cognitive Therapy:</i> Interventions to reinforce or promote desirable cognitive functioning or alter undesirable cognitive functioning	V. <i>Risk Management:</i> Interventions to initiate risk-reduction activities and continue monitoring risks over time	Z. <i>Childrearing Care:</i> Interventions to assist in rearing children	a. <i>Health System Management:</i> Interventions to provide and enhance support services for the delivery of care	d. <i>Community Risk Management:</i> Interventions that assist in detecting or preventing health risks to the whole community
C. <i>Immobility Management:</i> Interventions to manage restricted body movement and the sequelae	I. <i>Neurologic Management:</i> Interventions to optimize neurological functions	Q. <i>Communication Enhancement:</i> Interventions to facilitate delivering and receiving verbal and nonverbal messages		X. <i>Lifespan Care:</i> Interventions to facilitate family unit functioning and promote the health and welfare of family members throughout the lifespan	b. <i>Information Management:</i> Interventions to facilitate communication among health care professionals	

- D. Nutrition Support:**
Interventions to modify or maintain nutritional status
- E. Physical Comfort**
Promotion: Interventions to promote comfort using physical techniques
- F. Self-Care Facilitation:**
Interventions to provide or assist with routine activities of daily living
- J. Perioperative Care:**
Interventions to provide care before, during, and after surgery
- K. Respiratory Management:**
Interventions to provide care before, during, and immediately after surgery
- L. Skin/Wound Management:**
Interventions to maintain or restore tissue integrity
- M. Thermoregulation:**
Interventions to maintain body temperature within a normal range
- N. Tissue Perfusion Management:**
Interventions to optimize circulations of blood and fluids to the tissue
- R. Coping Assistance:**
Interventions to assist another to build on own strength, to adapt to a change in function, or to achieve a higher level of function
- S. Client Education:**
Interventions to facilitate learning
- T. Psychological Comfort**
Promotion: Interventions to promote comfort using psychological techniques

International (2009) nursing diagnoses for ease of use. For example, if a client has a nursing diagnosis of *acute pain*, 21 recommended interventions, including pain management, cutaneous stimulation, and anxiety reduction, may be used. A variety of nursing care activities are presented with each of the recommended interventions.

Planning Nursing Care

In any health care setting, a nurse is responsible for developing a written plan of care for clients. The written plan of care may take several forms (e.g., a nursing card-filing system, standardized care plans, or computerized plans). In general, a written **nursing care plan** includes nursing diagnoses; goals, expected outcomes, or both; and specific nursing interventions, so that any nurse is able to quickly identify a client's clinical needs and situation. In hospitals and community-based settings, the client often receives care from more than one nurse, physician, or allied health provider. A written nursing care plan makes possible continuity and coordination of nursing care and consultation by a number of health professionals.

Written care plans organize information exchanged by nurses in change-of-shift reports (see Chapter 16). You will learn to focus your reports on the nursing care, treatments, and expected outcomes documented in your care plans, and the end-of-shift report allows for discussion of care plans and the overall progress with the next caregiver. The nursing care plan (Box 13-4) provides an example of a care plan for Ms. Devine.

When developing an individualized care plan, involve the client and family, if feasible. The family is a resource for helping the client meet health care goals. In addition, meeting some of the family's needs may improve the client's level of wellness.

Institutional Care Plans

Institutional care plans become part of a client's legal medical record. Many hospitals still use a written Kardex nursing care plan. The **Kardex** card-filing system allows quick reference to the needs of the client for certain aspects of nursing care (see Chapter 15). The care plan section of a Kardex system varies by agency and focuses on planned interventions to meet the needs of the client and family and to prepare the client for discharge from the hospital. The focus of a nursing care plan differs by setting and the evolving client situation. For example, nursing care plans developed for clients returning home are usually based solely on long-term health needs. Nursing care plans for same-day surgeries are usually focused on clients' short-term needs (e.g., immediate recovery from surgery and instructions for self-care at home). In a long-term care facility, plans of care focus on clients' long-term rehabilitation needs.

Computerized Care Plans. A majority of health care facilities now have some type of electronic health record (EHR) and documentation system (Health Canada, 2009). Software programs are available for nursing care plans. In many facilities, the format is for standardized care plans that list generalized nursing diagnoses, goals, outcome criteria, and interventions for specific clients. You need to add or delete information by making selections from menus on the standardized form to individualize it for a client's needs. Computerized and standardized nursing care plans organize and enhance care planning. Their design incorporates current evidence-informed practice guidelines to achieve the desired client outcomes for a specific group of clients.

Care Plans for Community-Based Settings. Planning care for clients in community-based settings—for example, clinics, community centres, or clients' homes—involves using the same principles of nursing practice. In these settings, however, you need to complete a more comprehensive community, home, and family assessment. The client or family unit must be able to provide the majority of health care independently or with external resources provided to meet care demands (see Chapter 4).

Critical Pathways. Critical pathways are multidisciplinary treatment plans that outline treatments or interventions that clients may require for treatment of a condition. Most pathways are based on medical rather than nursing diagnoses, but they incorporate related nursing diagnoses and associated nursing interventions. A critical pathway maps out, day to day or even hour to hour, the recommended interventions and expected outcomes. For example, a pathway for a surgical procedure such as a bowel resection will recommend on a day-by-day basis the client's activities, procedures, and discharge planning activities. A critical pathway improves continuity of care because it clearly maps out the responsibility of each health discipline and can be used to monitor a client's progress. Well-developed pathways incorporate current evidence in caring for clients with a specific condition. When critical pathways are used to plan care, some forms of documentation are eliminated (e.g., the nursing care plan, flow sheets, and nurses' notes) because all of the pertinent components are included in the pathway.

Concept Maps

Concept maps and their use in care planning are described in Chapter 12. The concept map organizes and categorizes nursing concepts to give you a holistic view of your client's health care needs and to help you make better clinical decisions in planning care (Pilcher, 2009). There are different approaches to writing concept maps. A tool for developing your own concept map can be found on the Evolve Web site. Schuster (2003) has suggested some simple steps in preparing for concept mapping and in developing a clinical plan of care:

1. Retrieve the clinical assessment database from the medical record, including health history, physical assessment data, laboratory and diagnostic data, medication history, and treatment plan.
2. Review all information concerning health problems, treatments, and medications in the literature, course textbooks, pharmacology texts, and other resources.
3. On the nursing unit, review standardized nursing care plans, critical pathways, clinical protocols, or client education materials.
4. Develop a preliminary diagram of the client's chief medical diagnosis and the patterns of assessment data that you have gathered. Write the client's major medical diagnoses in the middle of the map, and then add the assessment patterns like spokes on a wheel (see Chapter 12). Identify and group the related patterns of clinical assessment and medical history data. Sometimes symptoms apply to more than one nursing diagnosis. Repeat symptoms under different categories when appropriate: for example, when pain is a symptom of both a problem with comfort and a problem with mobility.
5. Review your assessment patterns and attempt to identify the nursing diagnoses (see Chapter 12). Do not worry if you have difficulty developing nursing diagnoses at first. It is

► BOX 13-4 NURSING CARE PLAN

Acute Pain

Assessment

Ms. Devine is a 52-year-old woman who was injured in a fall two months ago that caused rupture of a lumbar disc. She is scheduled for a lumbar laminectomy this afternoon. Ms. Devine is the office manager for a realty business she runs with her husband. She was

not able to work regularly over the first month after the injury. She has sciatic pain that is sharp and burning, radiating down from her right hip to her right foot. The pain worsens when she sits. Her vital signs are as follows: temperature 37.3°C; blood pressure, 138/82 mm Hg; pulse, 84 beats per minute; and respirations, 24 breaths per minute.

Assessment Activities

Observe client's body movements.

Findings and Defining Characteristics*

Client limps *slightly with right leg*. Turns in bed slowly.

Observe client's facial expression.

Client *grimaces* when she attempts to sit down.

Ask client to rate pain at its worst.

Client *rates pain on a scale of 0 to 10 at an 8 or 9 at its worst*.

*Defining characteristics are in italic type.

Nursing Diagnosis: Acute pain related to pressure on spinal nerves

Planning

Goal (Nursing Outcomes Classification)[†]

Pain Control

Client will achieve improved pain control before surgery.

Expected Outcomes

Knowledge of Treatment Procedures

Client's self-report of pain will be 3 or less on a scale of 0 to 10.

Client's facial expressions reveal less discomfort when turning and repositioning.

[†]Outcomes classification labels from Moorhead, S., Johnson, M., Maas, M., & Swanson, E. (Eds.). (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Mosby.

Interventions (Nursing Interventions Classification)[†]

Analgesic Administration

Set positive expectations regarding effectiveness of analgesics.

Optimizes client's response to medication (Bulechek et al., 2008).

Give analgesic 30 minutes before turning or positioning client and before pain increases in severity.

Medication will exert peak effect when client increase movement.

Pain Management

Reduce environmental factors in client's room (e.g., noise, lighting, temperature extremes).

Pleasurable sensory stimuli reduce pain perception.

Offer client information about any procedures and efforts at reducing discomfort.

Information satisfies client's interests and enables client to evaluate and communicate pain (McCaffery & Pasero, 1999).

Progressive Muscle Relaxation

Direct client through progressive muscle relaxation exercise.

Coach client through exercise.

Relaxation techniques enable self-control when pain develops, reversing the cognitive and affective-motivational component of pain perception.

[†]Intervention classification labels from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Mosby.

Evaluation

Nursing Actions

Ask client to report severity of pain 30 minutes after analgesic administration.

Client Response and Finding

Ms. Devine reports pain at a level 5 on a scale of 0 to 10.

Achievement of Outcome

Pain is reduced, necessitates further nonpharmacological intervention to achieve outcome.

Observe client's facial expressions.

Ms. Devine is observed to have a relaxed facial expression.

Client's level of comfort is improving.

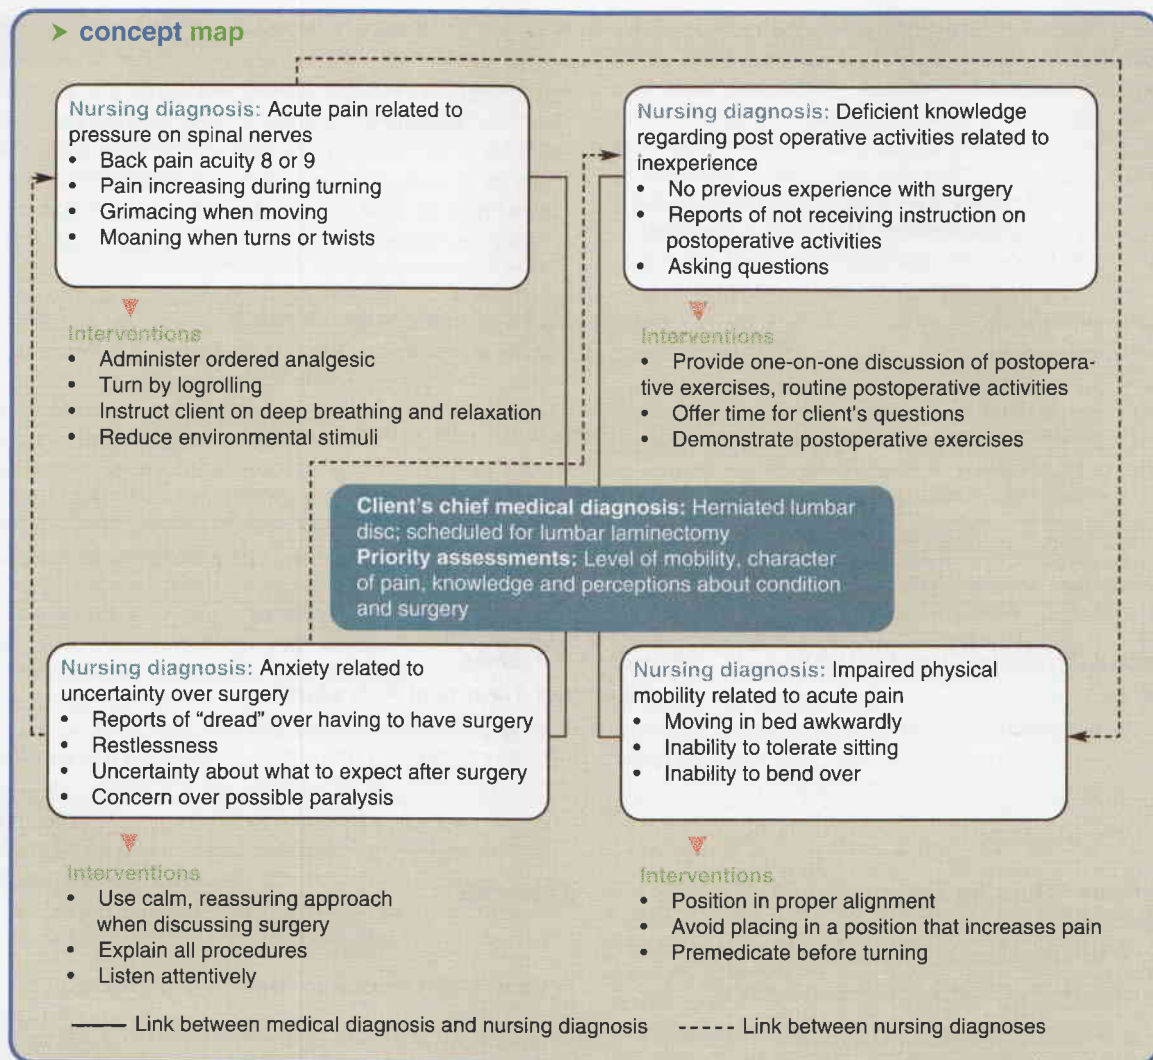

Figure 13-4 Concept map for planning Ms. Devine's nursing care.

important to recognize the major nursing care focus for the client. Add diagnostic statements later if necessary.

6. Analyze relationships among nursing diagnoses, and draw dotted lines between them to indicate relationships (Figure 13-4). It is important for you to make meaningful associations between concepts because the links need to be accurate, meaningful, and complete. You need to be able to explain why nursing diagnoses are related. For example, in the case of Ms. Devine, anxiety and acute pain are interrelated, and pain is a cause of her reduced mobility.
7. List nursing interventions to attain the outcomes for each nursing diagnosis (see Figure 13-4). This step corresponds to the planning phase of the nursing process.
8. While caring for the client, use the map to write down the client's responses to each nursing activity. Note your clinical impressions and inferences about effectiveness of interventions and progress toward meeting expected outcomes.
9. Keep the concept map with you throughout the clinical day. As you revise the plan, take notes and add or delete nursing interventions. Use the information recorded on the map for your documentation of client care.

Concept maps help nurses link concepts such as nursing diagnoses and to identify relationships between them to organize and understand information.

Consulting Other Health Care Professionals

Planning involves **consultation** with members of the health team. Although consultation can occur at any step in the nursing process, it occurs most often during planning and implementation, when problems necessitating additional knowledge, skills, or resources arise. Consulting involves seeking the expertise of a specialist, such as a nurse educator, registered nurse, or clinical nurse specialist to identify ways of approaching and managing the planning and implementation of therapies.

Nurse consultants frequently offer advice about difficult clinical problems. For example, a nursing student will consult with the registered nurse assigned to the same client about ways to individualize interventions, with a clinical specialist for wound care techniques, or with an educator for useful teaching resources. Nurses are consulted for their clinical

expertise, client education skills, or staff education skills. Nurses also consult with other members of the health care team, such as physical therapists, nutritionists, and social workers.

Implementing Nursing Care

Lisa enters Ms. Devine's room to administer morphine sulphate ordered for her severe back pain. The client is probably not going to the operating room for another four to six hours, so Lisa aims to reduce the client's discomfort before then. Lisa administers the medication, using physical care principles to promote safety and prevent infection. She communicates with Ms. Devine in a calm and reassuring manner to allay anxiety. Lisa explains that she will return to Ms. Devine's room in about 30 minutes to help her turn and become comfortable and to offer basic instruction about anticipated postoperative routines. Lisa's interventions are designed to prepare Ms. Devine for her upcoming surgery.

Implementation. With a care plan based on clear and relevant nursing diagnoses, you initiate interventions that are most likely to achieve goals and expected outcomes needed to support or improve the client's health status. A **nursing intervention** is any treatment, based on clinical judgement and knowledge, to enhance client outcomes (Bulechek et al., 2008). Ideally, interventions are evidence informed (see Chapter 6), providing the most current, up-to-date, and effective approaches addressing client problems and include both direct and indirect care measures.

Direct care interventions are treatments performed through interactions with clients. For example, a client receives direct intervention in the form of medication administration, insertion of an intravenous infusion, or counselling during a time of grief. Indirect care interventions are treatments performed away from the client but on behalf of the client or group of clients (Bulechek et al., 2008). For example, indirect care measures include actions for managing the client's environment (e.g., safety and infection control), documentation, and interdisciplinary collaboration. Both direct and indirect care measures can be nurse-initiated, physician-initiated, and collaborative interventions. For example, client teaching is a direct, nurse-initiated intervention. The indirect intervention of consultation is a collaborative intervention.

Each intervention is rendered within the context of a client's unique situation. As you learn to intervene for a client, consider the context of the clinical situation. What is the client's particular situation? Why do you need to intervene in the clinical situation? How does the client perceive your proposed interventions? How can you support the client as you intervene? The answers to these questions enable you to deliver care compassionately and effectively with the best outcomes for your clients.

Critical Thinking in Implementation

The selection of nursing interventions involves complex decision making and is based on critical thinking to ensure that an intervention is correct and appropriate for the clinical situation. Even though you have planned a set of interventions for a client, good judgement, decision making, and reassessment are needed before each intervention is actually performed, understanding that clients' conditions sometimes change rapidly. Some points to consider when you work with clients to meet their needs are as follows:

- Review the set of all possible nursing interventions for the client's problem (e.g., for Ms. Devine's pain, Lisa considers analgesic administration, positioning, relaxation, and other nonpharmacological approaches).
- Review all possible consequences associated with each possible nursing action (e.g., Lisa considers that the analgesic may relieve pain, may have little or insufficient effect, or may cause an adverse reaction).
- Determine the probability of all possible consequences (e.g., if Ms. Devine's pain has decreased with analgesia and positioning in the past, it is unlikely adverse reactions will occur, and the intervention will probably be successful; however, if the client continues to remain highly anxious, her pain may not be relieved).
- Determine the effect of the intervention on the client (e.g., if the administration of an analgesic is effective, Ms. Devine will become less anxious and will be more responsive to preoperative instruction).

The selection and performance of nursing interventions for a client is part of clinical decision making. The critical thinking model described in Chapter 11 provides a framework for making decisions about nursing care. As you proceed with an intervention, you should consider the purpose of the intervention, the steps in performing the intervention correctly, and the client's health status (Figure 13-5). It is essential to know the clinical standards of practice of each agency because procedures and standards of practice vary considerably. The standards of practice are guidelines for nursing practice and sanction principles to provide safe and competent care.

Standard Nursing Interventions

To facilitate good care planning, systems of standard nursing interventions are available to help you. These are based on common health care problems for which standard interventions can serve as a reference point in determining what is necessary. Of more importance, if the standards are informed by evidence, interventions are more likely to improve client outcomes (see Chapter 6). Standard interventions, both nurse initiated and physician initiated, are available in the form of clinical guidelines or protocols, preprinted medical directives or standing orders, and NIC-based interventions.

Clinical Practice Guidelines and Protocols

A clinical guideline or protocol is a document that guides decisions and interventions for specific health care problems. The guideline or protocol is developed on the basis of an authoritative examination of current scientific evidence and assists nurses, physicians, and other health care professionals in making decisions about appropriate health care for specific clinical circumstances. Clinicians within a health care agency sometimes choose to review the scientific literature and their own standard of practice to develop guidelines and protocols in an effort to improve their standard of care. For example, a hospital develops a rapid assessment protocol to improve the identification and early treatment of clients suspected of having a stroke. Clinical practice guidelines also assist you in providing the best possible care. The *Best Practice Guidelines* developed by the Registered Nurses' Association of Ontario (RNAO) (2012) is an excellent example of these.

Figure 13-5 Critical thinking and the process of implementing care.

Medical Directives or Standing Orders

A **medical directive** or **standing order** is a statement of orders for the conduct of routine therapies, monitoring guidelines, or diagnostic procedures, or a combination of these, for specific clients with identified clinical problems. These statements direct client care in various clinical settings and must be approved and signed by the prescribing physician or health care professional. Medical directives or standing orders are common in critical care settings and other specialized practice settings in which clients' needs change rapidly and require immediate attention. Examples include those for preoperative blood tests, those for postoperative exercises and positioning, and those for certain medications (such as heparin) for blood coagulation. When these statements are in place, the critical care nurse may administer the specified medication or conduct the specified action without first notifying the physician. Medical directives or standing orders are also common in community health settings in which physicians are not immediately available for consultation. Medical directives, standing orders, and clinical protocols give the nurse legal protection to intervene appropriately in the client's best interest.

Nursing Intervention Classifications System

The NIC system developed at the University of Iowa helps differentiate nursing practice from the practice of other health care professionals (Box 13-5; see also Box 13-2). The NIC-based interventions are common interventions recommended for various NANDA International (2009) nursing diagnoses and care activities for NIC-based interventions. They define a level of standardization for nursing care across settings and for comparison of outcomes.

BOX 13-5

Purposes of the Nursing Interventions Classification (NIC)

1. Standardization of the nomenclature (e.g., labelling, describing) of nursing interventions. Standardizes the language nurses use to describe sets of actions in delivering client care.
2. Expansion of nursing knowledge about connections between nursing diagnoses, treatments, and outcomes. These connections will be determined through the study of actual client care through the use of a database that the classification will generate.
3. Development of nursing and health care information systems.
4. Teaching decision making to nursing students. Defining and classifying nursing interventions help teach beginning nurses how to determine a client's need for care and to respond appropriately.
5. Determination of the cost of services provided by nurses.
6. Planning for resources needed in all types of nursing practice settings.
7. Language to communicate the unique functions of nursing.
8. Link with the classification systems of other health care providers.

Adapted from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St Louis, MO: Mosby.

Implementation Process

Preparation for implementation ensures efficient, safe, and effective nursing care. Preparatory activities include reassessing the client, reviewing and revising the existing nursing care plan, organizing resources and care delivery, anticipating

and preventing complications, and implementing nursing interventions.

Reassessing the Client

Assessment is a continuous process that occurs each time you interact with a client. When you collect new data and identify a new client need, you modify the care plan. You also modify a plan when you resolve a client's health care need. During the initial phase of planning nursing care, the preliminary assessment may focus on one dimension of the client, such as level of comfort, or on one system, such as the cardiovascular system. Reassessment helps you decide whether the proposed nursing action continues to be appropriate for the client's level of wellness. For example, Lisa plans to spend a few minutes talking further with Ms. Devine about her concerns relating to surgery. However, her reassessment reveals that Ms. Devine is still a bit uncomfortable and fatigued, and so Lisa must postpone her discussion. She decides to discuss Ms. Devine's concerns when she begins preoperative teaching in 30 minutes.

Reviewing and Revising the Existing Nursing Care Plan

After reassessing a client, review the care plan, compare assessment data in order to validate the nursing diagnoses, and determine whether the nursing interventions remain the most appropriate for the client's situation. If the client's status has changed and the nursing diagnosis and related nursing interventions are no longer appropriate, modify the nursing care plan. An outdated or incorrect care plan compromises quality of nursing care. Review and modification enables you to provide timely and appropriate nursing interventions. Modification of the existing written care plan has four steps:

1. Revise data in the assessment column to reflect current status. Date any new data to communicate the time of the change.
2. Revise the nursing diagnoses. Delete those that are no longer relevant, and add and date any new ones.
3. Revise specific interventions that correspond to the new nursing diagnoses and goals.
4. Determine the method of evaluation for any outcomes achieved.

It has been 45 minutes since Ms. Devine received an analgesic for her pain. She reports less discomfort, so Lisa initiates preoperative instruction. After about 10 minutes of discussion, Lisa notes that Ms. Devine expresses less concern about surgery; Ms. Devine says, "I feel better now that I understand what surgery involves." Ms. Devine's movements are calmer and less restless. Lisa enters her new findings into the care plan. However, she decides not to delete the nursing diagnosis of anxiety just yet and adds an intervention to her plan: Encourage verbalization of client's remaining concerns about surgery (see Figure 13-2). Seeing that Ms. Devine responded well to the analgesic, Lisa also adds more nonpharmacological interventions to her plan for pain management.

Organizing Resources and Care Delivery

A facility's resources include equipment and skilled personnel. Organization of equipment and personnel makes timely, efficient, skilled client care possible. Preparation for giving care involves preparing the environment, as well as clients.

Equipment. Most nursing procedures require some equipment or supplies. Before you perform an intervention, you must identify which supplies are needed, determine whether they are available, and ensure that equipment is in

working order and that you are skilled in operating the equipment to ensure safe use.

Personnel. You are responsible for determining whether to perform an intervention or to delegate it to another member of the nursing team. Your assessment of a client directs delegation decisions. For example, practical nurses are accountable and liable for their own practice and able to competently care for a stable and predictable clients. If you learned in the change-of-shift report that a particular client is experiencing cardiac irregularities, changing the client's status to unstable, you must assume primary care until the client's condition stabilizes (Canadian Nurses Association, 2011; College of Licensed Practical Nurses of Nova Scotia, 2011). Your judgement is important for determining the health status of the client and identifying the appropriate care provider.

Environment. A care environment needs to be safe and conducive to the implementation of therapies. Client safety is your first concern. You must anticipate circumstances that place clients at risk and create a culture of client safety (Canadian Client Safety Initiative, 2011). If the client has sensory deficits, a physical disability, or an alteration in level of consciousness, arrange the environment to prevent injury. Ensure privacy during procedures that may require some body exposure. Also, ensure that lighting is adequate for performing procedures correctly (see Chapter 36).

Client. Before you provide care, be sure the client is as physically and psychologically comfortable as possible. Ensure the client is comfortable during interventions. Control environmental factors at the outset, taking care of physical needs (e.g., elimination), minimizing the potential for interruptions, and positioning the client correctly. Consider the client's strength and endurance, and plan only the level of activity that the client is able to tolerate comfortably. Awareness of the client's psychosocial needs helps you create a favourable emotional climate. Some clients feel reassured by having a significant other present for encouragement and moral support.

Anticipating and Preventing Complications

Risks to clients arise from both illness and treatment. Be alert for and recognize these risks, adapt your choice of interventions to the situation, evaluate the benefit of the treatment in relation to the risk, and, finally, initiate risk-prevention measures (Figure 13-6). Many conditions heighten the risk for complications. For example, the client with preexisting left-sided paralysis that followed a stroke two years earlier is at risk for developing a pressure ulcer after orthopedic surgery because postoperative care entails traction and bed rest.

Your knowledge of pathophysiology and your experience with previous clients help you identify risk of complications. A thorough assessment reveals the level of the client's current risk. The scientific rationale, which concerns how certain interventions (e.g., pressure-relief devices, repositioning, or wound care) prevent or minimize complications, helps you select the most useful preventive measures. For example, if an obese client has uncontrolled postoperative pain, the risk for pressure ulcer development increases because the client may be unwilling or unable to change position frequently. The nurse anticipates when the client's pain will be aggravated, administers ordered analgesics, and then positions the client to remove pressure on the skin and underlying tissues. If the client continues to have difficulty turning or repositioning, the nurse may then select a pressure-relief device to place on the client's bed.

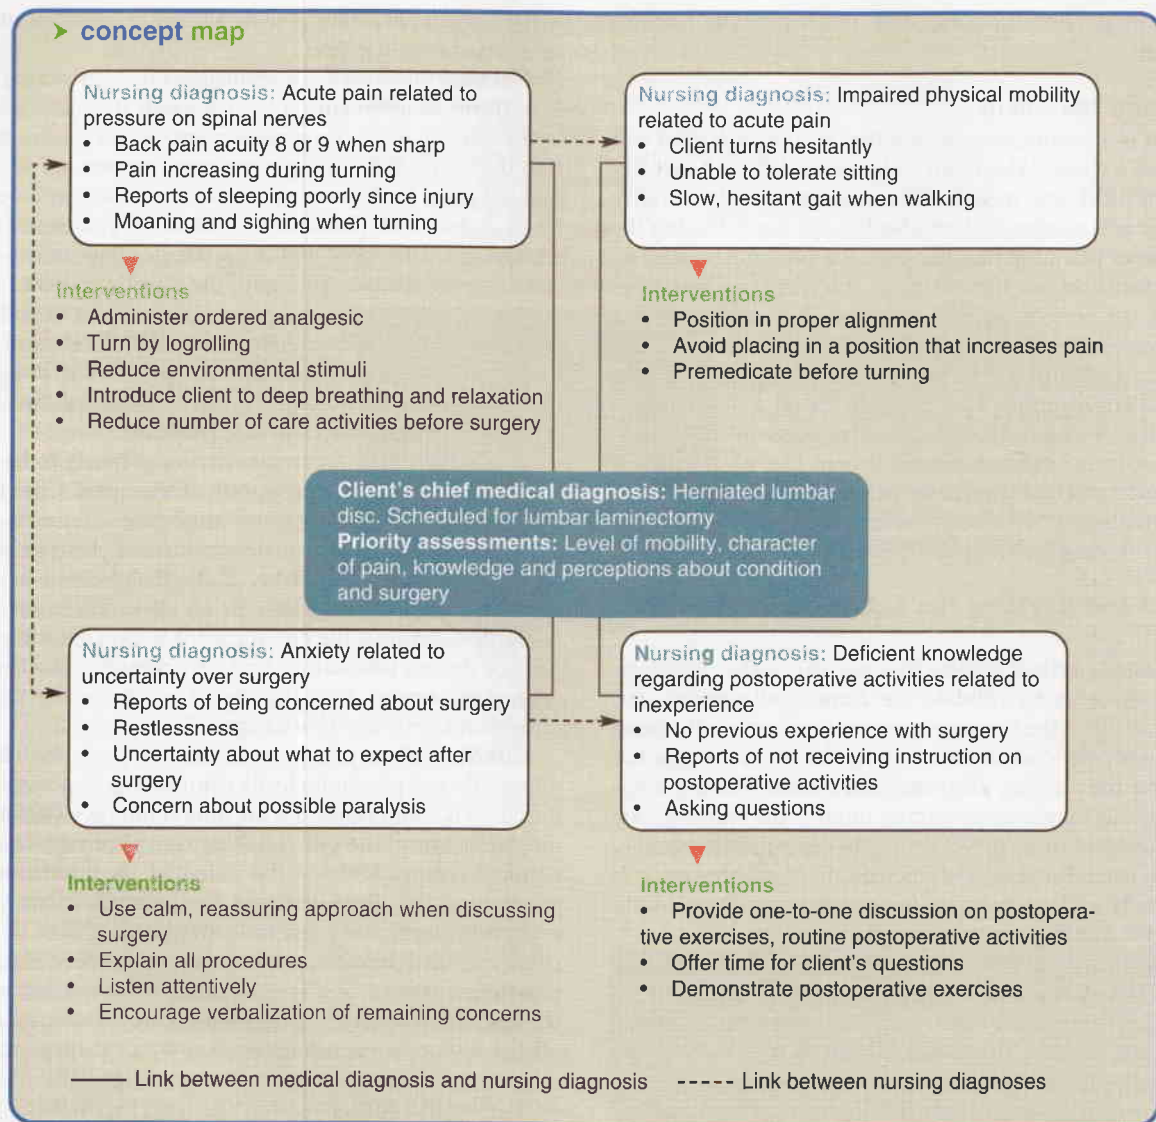

Figure 13-6 Concept map for planning Ms. Devine's postoperative nursing care.

Identifying Areas of Assistance. Certain nursing situations require you to obtain assistance by seeking additional knowledge, nursing skills, unregulated care providers, or a combination of these. Before you begin care, review the plan to determine the need for assistance. Sometimes you need assistance in performing a procedure, comforting a client, or preparing the client for a diagnostic test. For example, when you care for an overweight, immobilized client, you may require additional personnel to help turn and position the client safely. Be sure to determine the number of additional personnel in advance by consulting with other members of the health care team.

You require additional knowledge and skills in situations with which you are less familiar or experienced. In these situations, you need to prepare by seeking the necessary knowledge and requesting assistance from a more experienced nurse.

Implementation Skills

Nursing practice includes cognitive, interpersonal, and psychomotor (technical) skills. You need each type of skill to

implement direct and indirect nursing interventions. You are responsible for knowing which skill is needed in a particular situation and for having the necessary knowledge and ability to perform each one.

Cognitive Skills. Cognitive skills involve the application of critical thinking in the nursing process. To perform any intervention, always use good judgement and make sound clinical decisions. No nursing intervention is automatic or routine. You must continually think and anticipate so that you individualize care for clients. For example, Lisa knows the pathophysiological process of a ruptured disc, the anatomy of the spinal cord, and normal pain mechanisms. She considers each of these as she observes Ms. Devine, noting how the client's movement, posture, and position either aggravate or lessen her back pain. Lisa focuses on relieving Ms. Devine's acute pain with an analgesic but then considers the noninvasive interventions needed to minimize stress on the back so that the client will remain comfortable.

Interpersonal Skills. Interpersonal skills are essential for effective nursing action. The nurse develops a trusting

relationship, expresses a caring attitude, and communicates clearly with the client and family (see Chapter 18). Good interpersonal communication is crucial for keeping clients informed, providing individualized client teaching, and effectively supporting clients with challenging emotional needs.

Psychomotor Skills. Psychomotor skills require the integration of cognitive and motor activities. For example, when giving an injection, you need to understand anatomy, physiology, and pharmacology (cognitive skills) and use good coordination and precision to administer the injection correctly (motor skills). You are responsible for acquiring necessary psychomotor skills, through your experience in the nursing laboratory, through the use of interactive instructional technology, or through actual hands-on care of clients. In the case of a new skill, always assess your level of competency and obtain the necessary resources to ensure that the client receives safe treatment.

Direct Care

Nurses provide a wide variety of direct care measures. How a nurse interacts affects the success of any direct care activity, and a caring approach is essential. You need to be sensitive at all times to a client's clinical condition, values and beliefs, expectations, and cultural views. All direct care measures require safe and competent practice.

Activities of Daily Living

Activities of daily living (ADLs) are activities usually performed in the course of a normal day, including ambulation, eating, dressing, bathing, brushing the teeth, and grooming (see Chapter 37). A client's need for assistance with ADLs is temporary, permanent, or rehabilitative. A client with impaired mobility because of bilateral arm casts has a temporary need for assistance. A client with an irreversible injury to the cervical spinal cord is paralyzed and thus has a permanent need for assistance. Occupational and physical therapists play key roles in rehabilitation to restore ADL function.

When your assessment reveals that a client is experiencing fatigue, a limitation in mobility, confusion, and pain, the client needs assistance with ADLs. For example, a client who experiences shortness of breath avoids eating because of the associated fatigue. Assist the client by setting up meals, offering to cut up food, and planning for small and frequent meals to maintain nutrition. Determine the client's preferences when you assist with ADLs, and let the client participate as much as possible. Involving the client in planning the timing and types of interventions enhances the client's self-esteem and willingness to assume more independence.

Instrumental Activities of Daily Living

Illness or disability sometimes alters a client's ability to be independent in society. **Instrumental activities of daily living (IADLs)** include such skills as shopping, preparing meals, writing cheques, and taking medications. Nurses within the home care and community health care settings frequently assist clients in finding ways to accomplish IADLs. Often, family and friends are excellent resources for assisting clients. In acute care, it is important to anticipate how illness will affect the client's ability to perform IADLs and to involve other health professionals such as occupational therapists or social workers.

Physical Care Techniques

You routinely perform a variety of physical care techniques when caring for a client. Examples include turning and positioning, changing dressings, administering medications, and providing comfort measures. Considerations in providing physical care include protecting yourself and the client from injury, using infection control practices, following applicable practice guidelines, and staying organized. To carry out a procedure, you need to be knowledgeable about the procedure and how to perform it and about the expected outcomes.

Life-Saving Measures

A **life-saving measure** is a physical care technique performed when a client's physiological or psychological state is threatened (see Chapter 38). The purpose of life-saving measures is to restore physiological or psychological equilibrium. Such measures include administering emergency medications, instituting cardiopulmonary resuscitation, intervening to protect a confused or violent client, and providing a safe environment for a client experiencing a mental health crisis.

Counselling

Counselling is a direct care method that helps the client use a problem-solving process to recognize and manage stress and to facilitate interpersonal relationships. Counselling involves emotional, intellectual, spiritual, and psychological support. A client and family who need nursing counselling may be upset or frustrated, but they are not necessarily disabled psychologically. Family caregivers need assistance in adjusting to the physical and emotional demands of caregiving. Likewise, the recipient of care also needs assistance in adjusting to the disability. Clients with psychiatric diagnoses require therapy provided by psychiatric nurses or by social workers, psychiatrists, or psychologists.

Many counselling techniques foster cognitive, behavioural, developmental, experiential, and emotional growth in clients. Most of the techniques listed in Box 13-3 require additional knowledge beyond the scope of this text. Counselling encourages individuals to examine available alternatives and decide which choices are useful and appropriate.

Teaching

Teaching is an important nursing responsibility and is related to counselling. Both involve using communication skills to create a change in the client. However, in counselling, the focus is on the development of new attitudes and feelings, whereas in teaching, the focus is on intellectual growth or the acquisition of new knowledge or psychomotor skills (Redman, 2005).

The purpose of health teaching is to help clients learn about their health status, ways of promoting health, and ways of caring for themselves. Some common examples of teaching by nurses are related to medication administration, activity restrictions, health promotion activities (e.g., diet, exercise, or smoking cessation), and knowledge about disease and related implications. Your role includes assessment of clients' learning needs and readiness to learn. It is important to know your client and to be aware of cultural and social factors that influence a client's willingness and ability to learn. It is also important to know the client's health literacy levels: that is, whether the client can read directions or make calculations that sometimes are necessary with self-care skills. The teaching-learning process is an interaction between you and the client in which you address specific learning objectives (see Chapter 20).

Controlling for Adverse Reactions

An **adverse reaction** is a harmful effect of a medication, diagnostic test, or therapeutic intervention. You are responsible for knowing the potential adverse reactions associated with the nursing interventions you provide or perform for a client. Nursing actions that control for adverse reactions reduce or counteract the reaction. For example, when applying a moist heat compress, you must take steps to prevent burning the client's skin. First, assess the area where the compress is to be applied. Then inspect the area every five minutes for any adverse reaction, such as excessive reddening of the skin from the heat or skin maceration from the moisture of the compress. When completing a physician-initiated intervention, such as medication administration, you need to know about the potential side effects and adverse reactions of the medication. After administration of the medication, you evaluate the client for the expected outcomes and any side effects or adverse reactions. You need to be knowledgeable about medications that counteract the side effects or have adverse reactions. For example, a client has an unknown hypersensitivity to penicillin, and hives develop after three doses. You record the reaction, stop further administration of penicillin, and consult with the physician. You then anticipate an order for diphenhydramine (Benadryl), an antihistamine and antipruritic medication, to reduce the adverse reaction or allergic response and to relieve the itching.

Preventive Measures

Preventive nursing actions promote health and prevent illness in order to avoid the need for acute or rehabilitative health care. Prevention includes assessment and promotion of the client's health potential, carrying out prescribed measures (e.g., immunizations), health teaching, and identification of risk factors for illness, trauma, or both. Consider, for example, the case of Ms. Devine. Lisa learns that her client does not exercise regularly. Ms. Devine is 167.6 cm tall and weighs 72.7 kg. Because she is overweight and inactive, she is at risk when she performs activities that place stress on her back. If the client is able to lose some weight and start exercise therapy, she will be less likely to reinjure her back. Lisa plans to consult with the surgeon and physical therapist after surgery to design a plan to help Ms. Devine with weight loss and strengthening of back muscles.

Indirect Care

Indirect care measures are actions that support the effectiveness of direct care interventions (Bulechek et al., 2008). Nurses spend a good amount of time in indirect care activities (Box 13-6). Communication of information about clients (e.g., change-of-shift report and consultation) is essential to ensure that direct care activities are planned, coordinated, and performed with the proper resources.

Communicating Nursing Interventions

Any intervention you provide for a client will be communicated in a written or oral format, or both. Written interventions are part of both the nursing care plan and the permanent medical record. In a nursing care plan, there are collaborative interventions that represent the contributions of all disciplines involved in caring for a client. For example, when Ms. Devine begins recovering from back surgery, her nursing diagnosis of *impaired physical mobility* will identify interventions initiated

- Delegation of care activities to unregulated care providers
- Medical order transcription
- Infection control (e.g., proper handling and storage of supplies, use of protective isolation)
- Environmental safety management (e.g., make client rooms safe, strategically assigning clients in a geographic proximity to a single nurse)
- Computer data entry
- Telephone consultations with physicians and other health care providers
- Change-of-shift report
- Collecting, labelling, and transporting laboratory specimens
- Transporting clients to procedural areas and other nursing units

Adapted from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (2008). *Nursing interventions classification (NIC)* (5th ed.). St Louis, MO: Mosby.

by nurses (e.g., nonpharmacological pain control and positioning), by the surgeon (e.g., activity guidelines and pharmacological pain control), and by the physical therapist (e.g., ambulation training and exercises).

After completing nursing interventions, you document the treatment and client's response in the appropriate record (see Chapter 15). The entry usually includes a brief description of pertinent assessment findings, the specific procedure, the time and details of the procedure, and the client's response. You also communicate nursing interventions verbally to other health care professionals. Unless communication is clear, concise, accurate, and timely, caregivers can be uninformed, interventions may be needlessly duplicated, procedures may be delayed, or tasks may be left undone.

Delegating, Supervising, and Evaluating the Work of Other Staff Members

Depending on the staffing system, not all of the nursing interventions may be performed by the nurse who develops the care plan. Some activities are delegated to other members of the health care team. Interventions such as skin care, ambulation, grooming, measuring vital signs in stable clients, and hygiene measures are examples of care activities that you may assign to unregulated care providers. When a nurse delegates aspects of a client's care to another staff member, the nurse assigning tasks is responsible for ensuring that each task is appropriately assigned and completed.

Achieving Client-Centred Goals

You implement nursing care to meet client-centred goals and outcomes. In most clinical situations, multiple interventions are necessary to achieve selected outcomes. Because clients' conditions may change rapidly, it is important to apply principles of care coordination, such as good time management, organizational skills, and appropriate use of resources, to ensure that you deliver interventions effectively and that clients achieve desired outcomes. Priority setting is also crucial in successful implementation because it helps you to anticipate and sequence nursing interventions when a client has multiple

nursing diagnoses and collaborative problems. Another way to achieve client-centred goals is to encourage and assist clients to follow their treatment plan. Consultation and collaboration are critical to achieving the client's goals and expected outcomes.

Effective discharge planning and teaching for clients and families require individualized care that is consistent with culture and health beliefs. The process should be initiated at the outset of care. Adequate and timely discharge planning and education of the client and family are the first steps in promoting a smooth transition from one health care setting to another or to home. To be effective with discharge planning and education, you individualize your care and take into consideration the various factors that influence a client's health beliefs. For example, to help Ms. Devine adopt better exercise habits when she returns home, Lisa needs to determine what knowledge and psychosocial factors may influence Ms. Devine to exercise when she returns home. Reinforcing successes with the treatment plan encourages clients to follow their care plans.

✦ KEY CONCEPTS

- During planning, you determine client-centred goals, set priorities, develop expected outcomes of nursing care, and develop a nursing care plan.
- Priority setting helps you anticipate and sequence nursing interventions when a client has multiple nursing diagnoses and collaborative problems.
- Multiple factors in the nursing care environment influence your ability to set priorities.
- Goals and expected outcomes provide clear direction for the selection and use of nursing interventions and provide focus for evaluation of the effectiveness of the interventions.
- In setting goals, the time frame depends on the nature of the problem, etiology, overall condition of the client, and treatment setting.
- A client-centred goal is singular, observable, measurable, time limited, mutual, and realistic.
- An expected outcome is an objective criterion for goal achievement.
- Care plans and critical pathways increase communication among nurses and facilitate the continuity of care from one nurse to another and from one health care setting to another.
- A concept map provides a visually graphic way to understand the relationship between a client's nursing diagnoses and interventions.
- The NIC taxonomy provides a standardization to assist you in selecting suitable interventions for clients' problems.
- Correctly written nursing interventions include actions, frequency, quantity, and method, and they specify the person to perform them.
- Consultation and collaboration increase your knowledge about a client's problem and help you learn skills and obtain the resources needed to solve the problem.
- Implementation is the step of the nursing process in which you provide direct and indirect nursing care interventions to clients.
- Clinical guidelines or protocols are evidence-informed documents that guide decisions and interventions for specific health care problems.
- During the initial phase of implementation, you reassess the client to determine whether the proposed nursing action is still appropriate for the client's level of wellness.
- To anticipate and prevent complications, you identify risks to the client, adapt interventions to the situation, evaluate the benefit of a treatment in relation to the risk, and initiate risk-prevention measures to create a culture of client safety.
- Successful implementation of nursing interventions requires you to use appropriate cognitive, interpersonal, and psychomotor skills.
- Counselling is a direct care method that helps clients use problem solving to recognize and manage stress and to facilitate interpersonal relationships.
- Preventive nursing actions include assessment and promotion of the client's health potential, application of prescribed measures (e.g., immunizations), health teaching, and identification of risk factors for illness, trauma, or both.

✦ CRITICAL THINKING EXERCISES

Shawn, a nurse, has two different clients. Mr. Gordon is a 52-year-old client who was admitted to the hospital after a motor vehicle accident. He suffered rib fractures and has a laceration along his right thigh. Shawn has identified the following nursing diagnoses: *ineffective breathing pattern related to chest pain*, *acute pain related to musculoskeletal trauma*, and *risk for infection related to open wound*. Shawn's second client, Ms. Lawrence, is a 63-year-old woman who had surgery yesterday evening for repair of a foot fracture. Her foot is in a cast. Ms. Lawrence's nursing diagnoses include *acute pain related to tissue swelling*, *impaired mobility related to restricted movement from cast*, and *deficient knowledge regarding cast care related to inexperience*. Ms. Lawrence will probably be discharged in the morning. She lives alone. Shawn begins to plan care by establishing goals and outcomes for the nursing diagnoses.

1. Between the two clients, which diagnoses are high priority and which ones are intermediate priority?
2. Of the two clients, which one has higher priority regarding pain management?
3. For the nursing diagnosis *deficient knowledge regarding cast care related to inexperience*, write one goal and two expected outcomes.

Sue is a nursing student. She is to care for Mr. Nelson, a 63-year-old client who was admitted to the hospital with congestive heart failure and pneumonia. He is receiving medications to improve his heart failure and intravenous antibiotics to treat his pneumonia. He reports becoming fatigued easily during care activities and states, "I feel short of breath if I try to do too much." Sue notes he has 3+ edema in his lower extremities. Sue has identified nursing diagnoses of *decreased cardiac output* and *activity intolerance*. Sue must still perform hygiene measures, change the client's intravenous dressing, get him up into a chair, and measure noontime vital signs.

1. Before she begins to intervene, how can Sue make Mr. Nelson more comfortable?
2. What objective data does Sue obtain as part of her nursing assessment? What nursing actions may be implemented based on this information?
3. Because Sue thinks that Mr. Nelson may be at risk of falling, she decides to get assistance from a colleague before trying to get him into a chair. This is an example of what type of implementation skill?
4. When changing Mr. Nelson's intravenous dressing, Sue cleans the insertion site in accordance with clinical practice guidelines and checks the site for signs of phlebitis. These steps are examples of what type of direct care measure?

✦ REVIEW QUESTIONS

- Sheila, a nurse, is assigned to a client who has returned from the recovery room after surgery for a colorectal tumour. After an initial assessment, Sheila anticipates the need to monitor the client's abdominal dressing, intravenous infusion, and function of drainage tubes. The client is in pain and will not be able to eat or drink until intestinal function returns. Sheila will have to establish priorities of care in which of the following situations? (*Choose all that apply.*)
 - The family comes to visit the client.
 - The client expresses concern about pain control.
 - The client's vital signs change, showing a drop in blood pressure.
 - The charge nurse approaches Sheila and requests a report at end of shift.
- Sheila's client signals with her call light. Sheila enters the room and finds that the drainage tube is disconnected, the intravenous line has 100 mL of fluid remaining, and the client has asked to be turned. Which of the following should Sheila perform first?
 - Reconnect the drainage tubing.
 - Inspect the condition of the intravenous dressing.
 - Improve the client's comfort and turn her onto her side.
 - Go to the medication room and obtain the next intravenous fluid bag.
- In her nursing care plan, Sheila writes expected outcomes for her client. Which of the following expected outcomes are written correctly? (*Choose all that apply.*)
 - Client will remain a febrile until discharge.
 - Intravenous site will be without phlebitis by the third post-operative day.
 - Provide incentive spirometry for deep breathing every two hours.
 - Client will report pain and turn more freely by the first postoperative day.
- The nurse writes an expected outcome statement in measurable terms. An example is
 - Client will be pain free
 - Client will have less pain
 - Client will take pain medication every four hours
 - Client will report pain acuity less than 4 on a scale of 0 to 10
- Collaborative interventions are therapies that require
 - Nurse and client intervention
 - Physician and nurse intervention
 - Client and physician intervention
 - Multiple health care providers
- Nurses are responsible for an individualized written plan of care for clients. It is most important for the nurse to
 - Use a critical pathway to provide a strict plan of care
 - Complete a concept map to comprehensively manage one problem at a time
 - Collaborate with the client and family in the development of the plan
 - Understand that nursing care plans are the same despite different settings and client situations
- A number of different types of nursing interventions may be incorporated into the plan of care. Which of the following interventions is an example of a specific lifesaving measure that the nurse may implement?
 - Administering analgesics
 - Restraining a violent client
 - Initiating stress-reduction therapy
 - Teaching the client how to take his or her pulse
- Environmental factors heavily affect a client's care. Your first concern for the client includes which of the following?
 - Safety
 - Nurse staffing
 - Confidentiality
 - Adequate pain relief
- The nurse may use a concept map when implementing a plan of care. What is the purpose and distinction of a concept map?
 - Quality assurance in the health care facility
 - Identification of the relation of client problems and interventions
 - Multidisciplinary communication
 - Provision of a standardized format for client problems

Evaluation of Nursing Care

Original chapter by Patricia A. Potter, RN, MSN, PhD, FAAN

Canadian content written by Debbie A. Brennick, RN, MN, Willena I. Nemeth, RN, MN, and S. Helen Fraser, RN, MN

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss the relationship between critical thinking and evaluation.
- Identify the five elements of the evaluation process.
- Explain the relationship between goals of care, expected outcomes, and evaluative measures in evaluating nursing care.
- Give examples of evaluation measures for determining a client's progress toward outcomes.
- Evaluate a set of nursing actions selected for a client.
- Describe how evaluation leads to discontinuation, revision, or modification of a plan of care.

When a plumber comes to a home to fix a leaking faucet, he or she turns on the faucet to determine the problem, changes or adjusts parts to the faucet, and then turns on the faucet once again to determine whether the leak is fixed. Similarly, after a client with a diagnosis of pneumonia completes a five-day dose pack of antibiotics, the physician often has the client return to the office to have a chest X-ray examination to determine whether the pneumonia has cleared. When a nurse delivers an intervention such as applying a warm compress to a wound, several steps are involved. The nurse assesses the appearance of the wound, determines the severity of the wound, applies the appropriate form of compress, and then returns to determine whether the condition of the wound has improved. These three scenarios depict what ultimately occurs during the process of **evaluation**. The plumber rechecks the faucet, the physician orders a chest X-ray film, and the nurse inspects the wound.

Evaluation involves two components: an examination of a condition or situation and then a judgement as to whether change has occurred. Ideally, after an intervention takes place, evaluation will reveal an improvement.

Chapters 12 and 13 describe how you use critical thinking skills to gather client data, form nursing diagnoses, develop a plan of care, and implement the care plan. Evaluation, the final step of the nursing process, is crucial for determining whether, after application of the nursing process, the client's condition or well-being improves. You apply all that you know about a client and the client's condition, as well as experience with previous clients, to evaluate whether nursing care was effective. *You conduct evaluative measures to determine whether expected outcomes were attained, not whether nursing interventions were completed.* The expected outcomes are the standards against which you judge whether goals have been met and if care is successful.

In the continuing case study, Lisa is now making final preparations to send Ms. Devine to the operating room. Lisa evaluates the interventions she has implemented for the goals of achieving pain control, reducing anxiety, improving mobility, and improving Ms. Devine's knowledge of postoperative activities. Lisa had returned to Ms. Devine's room 30 minutes after administering an analgesic. At that time, the client reported having pain at a level of 4 on a scale of 0 (none) to 10 (worst). Lisa had documented the expected outcome of reduction of pain to a level of 3. Lisa then implemented further non-pharmacological interventions. It is now two hours later, and Lisa finds Ms. Devine lying in bed with her eyes closed. The client awakens as Lisa enters and says, "I just had my eyes closed; I am ready to have my surgery." Lisa says, "Tell me how you are feeling." Ms. Devine responds, "I feel better, and I am a little less worried than when I first got here." Lisa says, "On a scale of 0 to 10, tell me how you would rate your pain now." Ms. Devine replies, "I would say about a 4; it is still there but not as sharp." Lisa continues, "You said you were feeling less worried." Ms. Devine says, "Yes, I think you have helped me feel less anxious. You know, surgery is nothing anyone wants to have, but I feel better knowing what to expect." Lisa observes that Ms. Devine is relaxed and does not grimace when she turns slightly to her side. Lisa asks, "Can you take just a moment to go over with me what we discussed about your care after surgery?" Ms. Devine responds, "Sure; that would be fine."

Critical Thinking and Evaluation

Evaluation is an ongoing process whenever you have contact with a client. Collaboration is a key component of the evaluation process. You gather subjective data from the client as well as objective data from the family and health care team members prior to and following an intervention; this ensures all facets of the client's health are considered. You also review knowledge regarding the client's current condition, treatment, resources available for recovery, and the expected outcomes. By referring to previous experiences caring for similar clients, you are in a better position to know how to evaluate your client's needs. Apply critical thinking qualities and standards to determine whether expected outcomes of care are achieved (Figure 14-1). If expected outcomes are achieved, the overall goals for the client also are met. Client behaviour and responses that you assessed before performing nursing interventions are compared with behaviour and responses that occur after you perform nursing care. Critical thinking directs you to analyze the findings from evaluation (Figure 14-2): Has the client's condition improved? Is the client able to improve, or do physical factors preventing recovery exist? To what degree does this

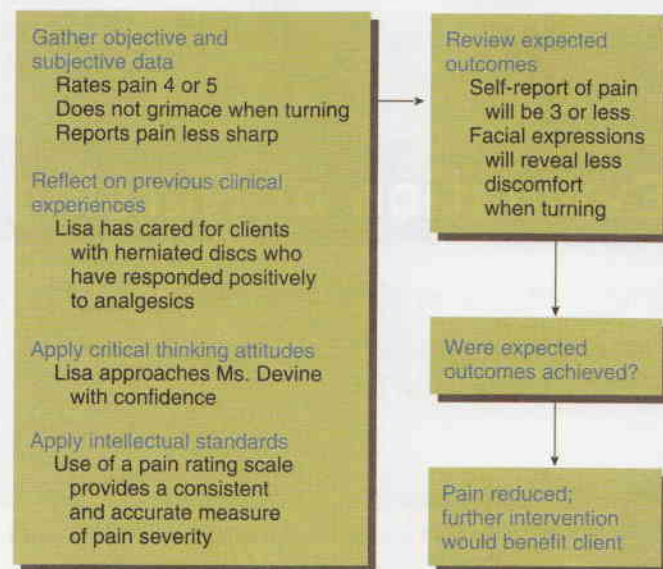

Figure 14-1 Critical thinking and the evaluation process.

client's motivation or willingness to pursue healthier behaviour influence response to therapies?

During evaluation, you make clinical decisions and continually redirect nursing care. For example, when Lisa evaluates Ms. Devine for a change in pain severity, she applies knowledge of the disease process, physiological responses to interventions (e.g., analgesics), and the correct procedure for pain severity measurement to interpret whether a change has occurred and whether the change is desirable. Lisa knows that the condition of the herniated disc will not change as a result of an analgesic, but the opioid medication she administered will alter the client's perception and reaction to pain (see Chapter 41). Use of the pain severity rating scale helps Lisa obtain an accurate measure of change in the client's pain perception. Evaluative findings determine Lisa's next course of action. In Ms. Devine's case, the pain score is a bit higher (4) than expected (3). However, the client is about to leave for surgery. Ms. Devine will probably receive a preoperative medication just before she goes to the preoperative holding area. The preoperative medication will include an analgesic, so Lisa knows she cannot administer an additional analgesic at this time. She evaluates that Ms. Devine's pain has been reduced and decides to continue to use basic comfort measures to afford further pain relief.

Positive evaluations occur when you meet desired outcomes, and they lead you to conclude that the nursing intervention or interventions effectively met the client's goals. For example, in the case study, Lisa notes that Ms. Devine's pain rating fell from an 8 or 9 to a 4. With an expected outcome of a pain severity of 3, Lisa's interventions showed a successful reduction in pain severity, but continuing intervention is necessary. Unmet or undesirable outcomes, such as the continuation of severe pain, indicate that interventions are not effective in minimizing or resolving the actual problem or avoiding the risk of a problem. Outcomes need to be realistic and adjusted on the basis of the client's prognosis and nursing diagnoses. An unmet outcome reveals the client has not responded to interventions as planned. As a result, you change the plan of care by trying different therapies or changing the frequency or

Figure 14-2 Critical thinking and evaluation.

approach of existing therapies. Reflecting on the success or failure of previous interventions will enhance your clinical expertise when choosing relevant evidence-informed options for future clients.

This sequence of critically evaluating and revising therapies continues until you and the client successfully and appropriately resolve the problems, as defined by nursing diagnoses. Remember that evaluation is dynamic and ever-changing, depending on the client's nursing diagnoses and condition. As problems change, so will expectations of outcomes. A client whose health status continuously changes requires more frequent evaluation. In addition, you will evaluate high-priority diagnoses first. For example, Lisa evaluates Ms. Devine's diagnosis of *acute pain* before evaluating the status of the diagnosis of *deficient knowledge*.

The Evaluation Process

The purpose of nursing care is to assist the client in resolving actual health problems, preventing the occurrence of potential problems, and maintaining a healthy state. The evaluation process, which determines the effectiveness of nursing care, consists of five elements: (1) identifying evaluative criteria and standards; (2) collecting data to determine whether the criteria or standards are met; (3) interpreting and summarizing findings; (4) documenting findings and any clinical judgement; and (5) terminating, continuing, or revising the care plan.

Identifying Criteria and Standards

You evaluate nursing care by critically analyzing the attainment of the client's identified goals and expected outcomes. A

client's goals and expected outcomes are the objective criteria by which to judge a client's response to care.

Goals. A goal is the expected behaviour or response that indicates resolution of a nursing diagnosis or maintenance of a healthy state. It is a summary statement of what will be accomplished when the client has met all expected outcomes. In the case of Ms. Devine, Chapter 13 described Lisa's plan of care for *acute pain*. Lisa selected the goal "Client achieves improved pain control before surgery." Successful achievement of this goal depends on the success of Lisa's interventions, chosen from the Nursing Interventions Classification (NIC) (Bulechek et al., 2008), for analgesic administration, pain management, and progressive muscle relaxation. Goals are also often based on standards of care or guidelines established for minimal safe practice. When a nurse cares for a client with a peripheral intravenous line, the goal "The intravenous site will remain free of phlebitis" is established on the basis of sound practice standards. (The Registered Nurses' Association of Ontario's [2012] *Best Practice Guidelines* contains specific recommendations for care and maintenance to reduce vascular access complications.)

Expected Outcomes. Outcomes have been broadly defined in the health care literature. Lewis et al. (2010) describe outcomes as merely the end product of health care. When nurses apply the nursing process, expected outcomes are the expected favourable and measurable results of nursing care. A nursing-sensitive client outcome is a measurable client or family state, behaviour, or perception largely influenced by and sensitive to nursing interventions (Moorhead et al., 2008). Examples of nursing-sensitive outcomes are reductions in pain severity, in incidence of pressure ulcers, in nosocomial

BOX 14-1 RESEARCH HIGHLIGHT

Nursing-Sensitive Outcomes

Evidence Summary

Nurses make significant contributions to the health care system, yet the powerful influence and impact of nurses remain virtually unknown. The College of Registered Nurses of Nova Scotia (CRNNS) recognizes the power of using evidence to influence health policy at provincial and national levels. The CRNNS is amassing a document that highlights recent nursing research and evidence related to (a) nurse staffing and client safety, (b) clinical outcomes research, and (c) studies examining the effects of nursing education and client outcomes (CRNNS, 2010). The discourse on nurse-sensitive outcomes highlights independent nursing functions that directly affect client outcomes. It is a valuable resource available to key stakeholders highlighting the contributions of registered nurses and nurse practitioners.

Application to Nursing Practice

An established database highlighting research related to nurse-sensitive outcomes will assist in the

- Development of best practices in client treatment plans
- Establishment of quality indicators of care
- Decision making related to staffing
- Planning of new programs and services

Reference: College of Registered Nurses of Nova Scotia. (2010, Revised). *Registered nurse-sensitive outcomes: A summary report*. Halifax: Author. Retrieved from http://www.crnns.ca/documents/FINAL_Report-RN_Sensitive_Outcomes_2010a%20_2_.pdf.

infections (e.g., *Clostridium difficile*) and in incidence of falls (Box 14-1). In comparison, outcomes influenced largely by medical interventions include client mortality, hospital readmissions, and length of stay. **Outcomes** are statements of progressive, step-by-step responses or behaviours that must be achieved in order to accomplish the goals of care. An outcome defines the effectiveness, efficiency, and measurement of the results of nursing interventions. When you achieve outcomes, the related factors for a nursing diagnosis usually no longer exist. In Ms. Devine's case, the expected outcomes for the goal of achieving improved pain control are "Client's self-report of pain will be 3 or less on a scale of 0 to 10" and "Client's facial expressions reveal less discomfort when turning and repositioning." When Lisa evaluates Ms. Devine's pain at a level of 4 and notes an absence of facial grimacing during turning, she knows the client's pain has been reduced but that further pain relief is needed. However, the related factor for Ms. Devine's diagnosis of *acute pain* is pressure on spinal nerves, which will not be totally relieved until surgery. The analgesics and non-invasive nursing interventions are designed to reduce the perception of pain from pressure on the nerves, as well as to minimize additional pressure on nerves. It is important to understand that evaluation is not a description of the achievement of an intervention. Evaluation of Ms. Devine does *not* involve observation of her ability to turn correctly; it *does* involve observation of the client's behaviour (facial expression) during turning. During the planning phase of the nursing process (see Chapter 13), it is important for you to select an observable client state, behaviour, or self-reported perception that will reflect goal achievement.

One valuable resource is the Nursing Outcomes Classification (NOC) (Moorhead et al., 2008), which provides a

TABLE 14-1

Linkages Between Nursing Outcomes Classification and Nursing Diagnoses

Nursing Diagnosis	Suggested Outcomes	Indicators (Examples)
Pain	Comfort level	Reported physical well-being Reported satisfaction with symptom control Expressed satisfaction with pain control
	Pain control	Recognition of pain onset Appropriate use of analgesics Control of reported pain
	Pain level	Reported pain severity Frequency of pain Muscle tension
Deficient knowledge	Knowledge: treatment procedures	Description of treatment procedures
	Knowledge: illness care	Description of disease process Description of prescribed activity

Adapted from Moorhead, S., Johnson, M., Maas, M., & Swanson, E. (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Mosby.

classification system of nursing sensitive outcomes. NOC is designed to provide the language for the evaluation step of the nursing process. The purposes of NOC are (1) to identify, label, validate, and classify nursing-sensitive client outcomes; (2) to field test and validate the classification; and (3) to define and test measurement procedures for the outcomes and indicators using clinical data. The NOC project complements the work of NANDA International (2009) and the NIC project. The NOC system offers nursing-sensitive outcomes for NANDA International nursing diagnoses (Table 14-1). For each outcome, the NOC system specifies recommended evaluation indicators: the client behaviours or responses that are measures of outcome achievement. Nurse-sensitive outcomes have far-reaching benefits and may aid in the development of health policy reflecting best practice and quality indicators of care (College of Registered Nurses of Nova Scotia [CRNNS, 2010]).

Collecting Evaluative Data

Proper evaluation enables you to determine the client's response to nursing care and whether the therapy was effective in improving the client's physical or emotional health. It is important to evaluate whether each client reaches a level of wellness or recovery that the health care team and client established in the goals of care. In addition, you must determine whether you met the client's expectations of care. You will ask clients questions about their perceptions of care, such as "Did you receive the type of pain relief you expected?" and "Did you receive enough information to care for your baby at home?" This level of evaluation is important for determining the client's satisfaction with care and for strengthening the partnering between you and the client. Always select appropriate evaluative measures to evaluate client response and expectations. Evaluating a client's response to nursing care requires the use of **evaluative measures**, which are simply

Figure 14-3 Evaluative measures. **A**, Nurse confirms client's medical history. **B**, Nurse evaluates client's lung sounds.

assessment skills and techniques (e.g., auscultation of lung sounds, observation of a client's skill performance, discussion of the client's feelings, and inspection of the skin) (Figure 14-3). In fact, evaluative measures are the same as assessment measures, but you perform them when you make decisions about the client's status and progress.

The intent of assessment is to identify any problems that exist. The intent of evaluation is to determine whether the known problems have remained the same, improved, worsened, or otherwise changed. In many clinical situations, it is important to collect evaluative measures over a period of time to determine whether a pattern of improvement or change exists. A one-time observation of a pressure ulcer is insufficient to determine that the ulcer is healing. It is important to note a consistency in change. For example, over a period of two days, you can observe whether the pressure ulcer is gradually decreasing in size, whether the amount of drainage is declining, and whether the redness of inflammation is resolving. Recognizing a pattern of improvement or deterioration allows you to reason and decide whether the client's problems are resolved. The primary source of data for evaluation is the client. However, you also use input from the family and other caregivers. For example, if a client is at home, you can ask a family member to report on the amount of food the client eats during a meal or how well a client prepares to take medications. You will sometimes consult with a colleague about how a hospitalized client responded to pain medication during another shift.

Interpreting and Summarizing Findings

During an acute illness, a client's clinical condition changes, often minute by minute. In contrast, chronic illness results in slow, subtle changes. When you evaluate the effect of interventions, you learn to recognize relevant evidence about a client's condition, even evidence that sometimes does not match clinical expectations. By applying your clinical knowledge and experience, you learn to recognize complications or adverse responses to illness and treatment in addition to expected outcomes. Using evidence, you make judgements about a client's condition. To develop clinical judgement, you learn to match the results of evaluative measures with expected outcomes to determine whether a client's status is improving. When interpreting findings, you compare the client's behavioural

responses and the physiological signs and symptoms you expect to observe with those you actually observe in your evaluation. Comparing expected and actual findings allows you to interpret and judge the client's condition and whether predicted changes have occurred (Table 14-2).

To objectively evaluate the degree of success in achieving outcomes of care, use the following steps:

1. Examine the outcome criteria to identify the exact desired client behaviour or response.
2. Assess the client's actual behaviour or response.
3. Compare the established outcome criteria with the actual behaviour or response.
4. Judge the degree of agreement between outcome criteria and the actual behaviour or response.
5. If the outcome criteria are not in agreement or are in only partial agreement with the actual behaviour or response, what are the barriers to agreement? Why was agreement not complete?

Evaluation is easier to perform after you care for a client over a long period. You are then able to make subtle comparisons of client responses and behaviours. When you have not had the chance to care for a client over an extended time, you improve evaluation by referring to previous experiences or asking colleagues who are familiar with the client to confirm evaluation findings. In short-term stay settings, a plan of care with clearly defined short- and long-term goals provides a framework to guide future care. The accuracy of any evaluation improves when you are familiar with the client's behaviour and physiological status or have cared for more than one client with a similar problem. Remember to evaluate whether each expected outcome was achieved and its place in the sequence of care. If you do not, it will be difficult to determine which expected outcome in the sequence was not achieved, and you cannot revise and redirect the plan of care at the most appropriate time. If the client achieves the expected outcomes, you either continue the care plan to maintain a therapeutic status or discontinue interventions because the goal of care is met. If evaluation reveals that the expected outcomes were not achieved or were only partially achieved, you begin reassessment and revision of the care plan. Goals are achieved in different degrees. If the client's response matches or exceeds the outcome criteria, the goal is met. If the client's behaviour begins to show changes but does not yet meet criteria set, the

▶ TABLE 14-2

Evaluative Measures to Determine the Success of Goals and Expected Outcomes

Goals	Evaluative Measures	Expected Outcomes
Client's pressure ulcer will heal within seven days	Inspect colour, condition, and location of pressure ulcer Measure diameter of ulcer daily Note odour and colour of drainage from ulcer	Erythema will be reduced in two days Diameter of ulcer will decrease in five days Ulcer will have no drainage in two days Skin overlying ulcer will be closed in seven days
Client will tolerate ambulation to end of hall by 11/20	Palpate client's radial pulse before exercise Palpate client's radial pulse 10 minutes after exercise Assess respiratory rate during exercise Observe client for dyspnea or breathlessness during exercise	Pulse will remain below 110 beats per minute during exercise Respiratory rate will remain within two breaths of client's baseline rate Client will deny feeling of breathlessness
Client will have improved grief resolution by 1/15	Ask client about frequency of periods of crying, sadness Review client's sleeping log Review client's dietary intake	Client reports decreased frequency of crying and sadness in two months Client has periods of six to seven hours of sleep without interruption within 10 days Client has no weight loss in one month

goal is partially met. If progress is not made, the goal is not met (Table 14-3).

Documenting Findings

Documentation and reporting are an important part of evaluation. For you to make ongoing clinical decisions, a client's medical record must contain accurate information. When documenting the client's response to interventions, always describe the same evaluative measures. Your aim is to present a clear description, informed by the evaluative data, of a client's progress or lack of progress. Written nursing progress notes, assessment flow sheets, and information shared between nurses during change-of-shift reports (see Chapter 15) communicate a client's progress toward meeting expected outcomes and goals for the nursing plan of care.

Care Plan Revision

Evaluate expected outcomes, and determine whether the goals of care have been met. Then decide whether you need to adjust the plan of care. If you meet a goal successfully, discontinue that portion of the care plan. If goals are unmet or partially met, you must continue intervention. After you evaluate a client, you may want to modify or add nursing diagnoses with appropriate goals and expected outcomes, and establish interventions. You must also redefine priorities. This is an important step in critical thinking: knowing how the client is progressing and how problems either resolve or worsen.

In the case of Ms. Devine, Lisa's initial evaluation at the beginning of this chapter revealed the following: the client reported feeling better, rated pain at a level of 4, was lying in bed relaxed, felt less worried, and did not grimace when turning over.

When matching these actual behaviours and responses to expected outcomes, Lisa determines that Ms. Devine's pain and anxiety have lessened. Because the pain is less acute, Ms. Devine's mobility is less restricted. However, Lisa knows that the cause of Ms. Devine's pain has not been corrected. The surgery is still pending, and thus the client's anxiety will possibly increase. Lisa decides to continue the plan of care but makes revisions by adding more basic comfort measures. The comfort measures help control both the pain and anxiety and help maintain the client's mobility. Lisa next evaluates whether

▶ TABLE 14-3

Examples of Objective Evaluation of Goal Achievement

Goals	Outcome Criteria	Client Response	Evaluation Findings
Client will self-administer insulin by 12/18	Client prepares insulin dosage in syringe by 12/17 Client demonstrates self-injection by 12/18	Client prepared accurate dosage in syringe on 12/17 Client administered morning insulin dosage and performed self-injection correctly on 12/18	Client has progressed and achieved desired behaviour
Client's lungs will be free of secretions by 11/30	Coughing will be nonproductive by 11/29 Lungs will be clear to auscultation by 11/30 Respirations will be 20 per minute by 11/30	Client coughed frequently and productively on 11/29 Lungs were clear to auscultation on 11/30 Respirations were 18 per minute on 11/29	Client will require continued therapy Condition is improving
Client will be able to perform self-care measures without discomfort in two days	Client will rate pain as 3 on a scale of 0-10 within two days Client will initiate bathing within two days	Client rates severe right-sided abdominal pain as 5 on a scale of 0-10 while attempting bathing on day 2	Client's condition still indicates a problem Client requires continued therapy with possibly new care measures

Ms. Devine remembers the postoperative activities that they discussed earlier: "Ms. Devine, we talked about several things that you will be asked to do after surgery. I want to know whether you understand what we discussed. Tell me what to expect about your pain control and activity." Ms. Devine responds, "You said that I would have a device that lets me control how much pain medication I receive. I should not be afraid to use it. I know the nurses will get me up early to move around. You said if I can get control of the pain, it will be easier to get up and walk. What I do not remember is something you said about breathing." Lisa says, "The pain control device you are referring to is called a PCA. As for breathing, let's practise deep breathing with the incentive spirometer one more time." Lisa recognizes that Ms. Devine has learned about select postoperative activities but requires further instruction on the incentive spirometer. Deficient knowledge now becomes Lisa's priority until Ms. Devine leaves for surgery.

Careful monitoring and early detection of problems are a client's first line of defence. Always make nursing judgements of your observations of what is occurring with a specific client and not merely of what happens to clients in general. Frequently, changes are not obvious. Evaluations are client specific, based on a close familiarity with each client's behaviour, physical status, and reaction to caregivers. Critical thinking skills promote accurate evaluation, which enables appropriate revision of ineffective care plans and discontinuation of therapy that has successfully resolved a problem.

Discontinuing a Care Plan

After you determine that expected outcomes and goals have been met, you confirm this finding with the client when possible. If you and the client agree, then you discontinue that portion of the care plan. Documentation of a discontinued plan ensures that other nurses will not unnecessarily continue interventions for that portion of the plan of care. Continuity of care ensures that care provided to clients is relevant and timely. If you do not communicate achieved goals, you will waste much time.

Modifying a Care Plan

When goals are not met, you identify the factors that interfere with goal achievement. A change in the client's condition, needs, or abilities usually necessitates alteration of the care plan. For example, when teaching self-administration of insulin, you discover that the client has developed a new problem, a tremor associated with a side effect of a medication. The client is unable to draw medication from a syringe or inject the needle safely. As a result, the original outcomes "Client will correctly prepare insulin in a syringe" and "Client will administer insulin injection independently" cannot be met. You introduce new interventions (instructing a family member in insulin preparation and administration or introduce an alternative method of insulin administration, such as an insulin pen) and revise outcomes to meet the goal of care.

At times a lack of goal achievement results from an error in nursing judgement or failure to follow each step of the nursing process. Clients often have multiple and complex problems. When a goal is not achieved, no matter what the reason, repeat the entire nursing process sequence for that nursing diagnosis to discover which changes in the plan are needed. You then reassess the client, determine accuracy of the nursing diagnosis, establish new goals and expected outcomes, and select new interventions while adhering to national and provincial nursing standards.

A complete reassessment of all client factors relating to the nursing diagnosis and etiology is necessary when you modify a plan. Reassessment requires critical thinking as you compare new data about the client's condition with previously assessed information.

Knowledge from previous experiences helps you direct the reassessment process. Caring for clients and families who have had similar health problems gives you a strong background of knowledge to use for anticipating client needs and knowing what to assess. Reassessment reveals "missing links" (i.e., critical pieces of new information that were overlooked, which thus interfered with goal achievement). You sort, validate, and cluster all new data to analyze and interpret differences from the original database. You also document reassessment data to alert other nursing staff to the client's status. After reassessment, determine what nursing diagnoses are accurate for the situation. Ask whether you selected the correct diagnosis and whether it and the etiological factor are current. Then revise the problem list to reflect the client's changed status.

Sometimes you make a new diagnosis. You base your nursing care on an accurate list of nursing diagnoses. Accuracy is more important than the number of diagnoses selected. As the client's condition changes, the diagnoses also change. For example, you identified the nursing diagnosis *deficient knowledge related to inexperience* for a client with newly diagnosed diabetes. The original plan was to instruct the client in how to self-administer insulin. After finding that the client has difficulty self-administering insulin because of a tremor associated with a side effect of a medication, you reassess the situation and find that a family member is available as a resource. To develop a plan designed to educate a caregiver about the administration of insulin, you then establish a new diagnosis: *ineffective health maintenance related to impaired dexterity*.

Goals and Expected Outcomes

When you revise care plans, review the goals and expected outcomes for needed changes. You even need to examine the appropriateness of goals for unchanged nursing diagnoses, because a change in one problem sometimes affects other problems. Determining that each goal and expected outcome is realistic for the problem, etiology, and time frame is particularly important. Unrealistic expected outcomes and time frames hamper goal achievement. Clearly document goals and expected outcomes for new or revised nursing diagnoses so that all team members are aware of the revised care plan. When the goal is still appropriate but has not yet been met, try changing the evaluation data to allow more time. You may also decide at this time to change interventions. For example, when a client's pressure ulcer does not show signs of healing, you choose to use a different support surface or a different type of wound cleanser. All goals and expected outcomes are client-centred, with realistic expectations for client achievement.

Interventions

The evaluation of interventions concerns two factors: the appropriateness of the interventions selected and the correct application of the intervention. The appropriateness of an intervention is based on the standard of care for a client's health problem. A **standard of care** is the minimum level of care acceptable to ensure high quality of care. Standards of care define the types of therapies typically administered to clients with defined problems or needs. If a client who is receiving chemotherapy for leukemia has a specific nursing diagnosis,

such as *nausea related to pharyngeal irritation*, the standard of care established by a nursing department for this problem includes pain control measures for pharyngeal irritation, mouth care guidelines, and diet therapy. The nurse reviews the standard of care to determine whether the right interventions have been chosen or whether additional ones are required. Increasing or decreasing the frequency of interventions is another approach for ensuring appropriate application of an intervention. You adjust interventions on the basis of the client's actual response to therapy, as well as previous experience with similar clients. For example, if a client continues to have congested lung sounds, you increase the frequency of the client's coughing and deep breathing exercises to remove secretions.

During evaluation, you find that some planned interventions are designed for an inappropriate level of nursing care. If you need to change the level of care, substitute a different action verb, such as *assist* in place of *provide* or *demonstrate* in place of *instruct*, in the revised care plan. For example, to assist a client to walk, a nurse must be at the client's side during ambulation, whereas providing an assistive device helps the client ambulate more independently. Also, demonstrating requires you to show a client how a skill is performed rather than simply telling the client how to perform it. Sometimes the level of care is appropriate but the interventions are unsuitable because of a change in the expected outcome. In this case, discontinue the interventions and plan new ones. Make any changes in the plan of care according to the nature of the client's unfavourable response. Consult with other nurses to obtain suggestions for improving the approach to care delivery. Senior nurses are often excellent resources because of their experience. Simply changing the care plan is not enough. Implement the new plan, and re-evaluate the client's response to the nursing actions. *Evaluation is continuous.*

On occasion, you will discover unmet client needs during evaluation. This is normal. The nursing process is a systematic, problem-solving approach to individualized client care, but many factors affect each client with health care problems. Clients with the same health care problem are not treated the same way. As a result, you will sometimes make errors in judgement. The systematic use of evaluation provides a way for you to catch these errors. By consistently incorporating evaluation into practice, you will minimize errors and ensure that the client's plan of care is appropriate and relevant.

The evaluation of nursing care is a professional responsibility, and it is a crucial component of nursing care. Evaluation that focuses on a single client's plan of care enables you as a nurse to know the effectiveness of interventions and whether expected outcomes are met. At a system or institutional level, evaluation involves quality improvement and performance improvement activities that focus on the delivery of care provided by an agency or a specific nursing division within an agency. Through the continuous evaluation of care, nurses play a key role in the ongoing improvement of client care.

❖ KEY CONCEPTS

- Evaluation is a step of the nursing process that allows nurses to determine whether nursing interventions are successful in improving a client's condition or well-being.
- During evaluation, the appropriateness of the intervention should be assessed, as should the outcome.
- Evaluation involves two components: an examination of a condition or situation and a judgement as to whether change has occurred.

- During evaluation, apply critical thinking to make nursing decisions and redirect nursing care to best meet clients' needs.
- Evaluation findings are positive when you meet desired outcomes; this enables you to conclude that your interventions were effective.
- When the client's actual response (e.g., behaviours and physiological signs and symptoms) to nursing interventions are compared with expected outcomes established during planning, you determine whether goals of care are met. At this time, you should also determine whether the goals, outcomes, or both were realistic.
- Evaluative measures are assessment skills or techniques that you use to collect data for evaluation.
- It sometimes becomes necessary to collect evaluative measures over time to determine whether a pattern of change exists.
- To interpret evaluative findings, examine the outcome criteria, assess the client's actual behaviour or response, compare the outcome criteria with the actual behaviour or response, and judge the degree of agreement.
- Documentation of evaluative findings allows all members of the health care team to know whether a client is progressing.
- As a result of evaluation, a client's nursing diagnoses, priorities, and interventions sometimes change.

❖ CRITICAL THINKING EXERCISES

1. Mr. Jacko has recently received a diagnosis of asthma and is to be discharged tomorrow. His physician has ordered a metered dose inhaler for Mr. Jacko to use daily. The client has not used an inhaler before. He asks the nurse, "What do I do at home if I have trouble using this thing?" The nursing diagnosis for Mr. Jacko is *deficient knowledge regarding use of a metered-dose inhaler related to inexperience*. Write a goal and expected outcome for this clinical scenario.
2. Mr. Vicar has been visiting the clinic for more than a month. He visits weekly for follow-up care for a chronic venous stasis ulcer of the left leg. The nurse's note at the time of his first visit contained the following information: "Ulcer with irregular margins, 4 cm wide by 5 cm long, approximately 0.5 cm deep, draining foul-smelling purulent yellowish drainage. Subcutaneous tissue visible. Skin around ulcer, brownish rust in colour. Zinc oxide and calamine gauze applied to ulcer; elastic wrap bandage applied to gauze. Client instructed to return in 1 week." The stated goal is "Wound will demonstrate healing within 4 weeks." As the nurse who is caring for the client on the follow-up visit, what expected outcomes would you anticipate for this goal? What evaluative measures would you use to determine whether the wound is healing?

❖ REVIEW QUESTIONS

1. A nurse caring for a client with pneumonia sits the client up in bed and suctions the client's airway. After suctioning, the client describes some discomfort in his abdomen. The nurse auscultates the client's lung sounds and provides a glass of water for the client. Which of the following is an evaluative measure used by the nurse?
 1. Suctioning the airway
 2. Sitting client up in bed
 3. Auscultating lung sounds
 4. Asking client to describe type of discomfort

2. A nurse caring for a client with pneumonia sits the client up in bed and suctions the client's airway. After the suctioning, the client describes some discomfort in his abdomen. The nurse auscultates the client's lung sounds and provides a glass of water to the client. Which of the following is an appropriate evaluative criterion used by the nurse? (*Choose all that apply.*)
 1. The client drinks the contents of the water glass.
 2. The client's lungs are clear to auscultation in bases.
 3. The client reports abdominal pain on scale of 0 to 10.
 4. The client's rate and depth of breathing are normal with the head of the bed elevated.

3. The evaluation of nursing care is a professional responsibility and crucial to determining whether, after application of the nursing process, the client's condition or well-being improves. One of the five elements of the evaluation process is "identifying evaluative criteria and standards." On what objective criteria does the nurse base judgement of a client's response to care?
 1. Goals and expected outcomes
 2. Client states "I am feeling better."
 3. Nursing diagnosis
 4. Effective communication by the client

4. Mr. Gunderson returns to the walk-in clinic after taking a seven-day course of antibiotic therapy and is still exhibiting signs of pneumonia. What should be the nurse's initial action?
 1. Arrange for the physician to order a different antibiotic.
 2. Obtain another sputum specimen for a culture and sensitivity.
 3. Determine if Mr. Gunderson took the medication as prescribed.
 4. Make an appointment for Mr. Gunderson to be seen by the physician.

5. When Mr. Gould, a First Nations person, was admitted to hospital he was provided with a regular diet consisting of three traditional meals a day. After a week it was identified that Mr. Gould was eating only 40% of the meals and was losing weight. What should the nurse do?
 1. Request Mr. Gould's family assist with the meals until meals are completed
 2. Schedule several between meal supplements
 3. Change the plan of care to provide five small meals reflecting Mr. Gould's cultural preferences
 4. Secure an order to increase the number of calories provided

❖ RECOMMENDED WEB SITES

Canadian Nurses Association (CNA): http://www2.cna-aiic.ca/CNA/practice/standards/default_e.aspx

This expansive nursing Web site provides comprehensive information regarding many nursing issues such as nursing care delivery models and standards and best practices. The CNA's *Code of Ethics for Registered Nurses* is an example of the type of documents available on this site.

Center for Nursing Classification & Clinical Effectiveness: http://www.nursing.uiowa.edu/excellence/nursing_knowledge/clinical_effectiveness/index.htm

The University of Iowa's Center for Nursing Classification & Clinical Effectiveness was established to facilitate ongoing research of the Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC). This Web site provides an overview of the NIC and NOC and offers information about new classification material and publications.

NANDA International: <http://www.nanda.org/>

Through this Web site, NANDA International provides current information on nursing diagnosis research, publications, support resources, and Internet resources.

Registered Nurses' Association of Ontario: Nursing Best Practice Guidelines: <http://www.rnao.org>

The Registered Nurses' Association of Ontario has developed an extensive process for developing best practices guidelines in a variety of areas of clinical nursing. They have received federal and provincial funding for this process, and the results of their work have been made available to all Canadian nurses through this Web site, which lists all current guidelines that have been developed.

College of Registered Nurses of Nova Scotia (CRNNS): Registered Nurse-Sensitive Outcomes: <http://www.crnns.ca/>

The College of Registered Nurses of Nova Scotia establishes and maintains the standards for nursing practice that registered nurses must meet to ensure the safe and ethical delivery of competent nursing care. The CRNNS Web site provides a plethora of resources for members designed to help them maintain a high level of excellence in practice.

Documenting and Reporting

Original chapter by Frank Lyerla, RN, PhD

Canadian content written by Maureen A. Barry, RN, MScN

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Describe multidisciplinary communication within the health care team.
- Identify purposes of a health care record.
- Discuss legal guidelines for documentation.
- Identify ways to maintain confidentiality of records and reports.
- Describe six quality guidelines for documentation and reporting.
- Describe the different methods used in record keeping.
- Discuss the advantages of standardized documentation forms.
- Identify elements to include when documenting a patient discharge plan.
- Describe the role of critical pathways in multidisciplinary documentation.
- Identify the important aspects of home care and long-term care documentation.
- Discuss the role of computerized charting and use of electronic health records in documentation.
- Describe the purpose and content of a change-of-shift report.
- Explain how to verify telephone orders.

Documentation is anything written or electronically generated that describes the status of a patient or the care or service given to that patient. Documentation within a patient health care record is a vital aspect of nursing practice. According to Hendrich et al. (2008), more than 35% of nursing practice time is concerned with documentation. Nursing documentation must be accurate, comprehensive, and flexible enough for members of the health care team to retrieve critical data,

maintain continuity of care, and track patient outcomes, and it must reflect current standards of nursing practice. Information in the patient record provides a detailed account of the quality of care delivered to patients. Documentation ensures continuity and quality of care, furnishes legal evidence of care, provides evidence for quality assurance purposes, and constitutes a database for planning future health care (Cheevakasemsook et al., 2006).

Effective documentation can positively affect the quality of life and health outcomes for patients and minimize the risk of errors. Accrediting agencies such as Accreditation Canada offer guidelines for documentation. However, documentation and reporting practices differ among institutions and jurisdictions and are influenced by ethical, legal, medical, and agency guidelines.

As a member of the health care team, you need to communicate information about patients accurately and in a timely, effective manner. The quality of patient care depends largely on the caregivers' ability to communicate with one another. All health care providers require accurate information about patients in order to devise an organized, comprehensive care plan. If the care plan is not communicated to all members of the health care team, care can be fragmented, tasks repeated, and therapies delayed or omitted. Data recorded, reported, or communicated to other health care providers are confidential, and the confidentiality of these data must be protected.

The health care environment creates many challenges to accurately documenting and reporting patient care. Because of the quality of care, the standards of regulatory agencies and nursing practice, and the legal guidelines for nursing practice, documentation and reporting are critical responsibilities of a nurse.

Confidentiality

Whether the transfer of patient information occurs through verbal reports, written documents, or electronic transfer, nurses must follow certain principles to maintain confidentiality of information. You are legally and ethically obligated to keep information about patients confidential. You may not discuss a patient's examination, observation, conversation, or treatment with other patients or with staff who are not involved in the patient's care. Only staff directly involved in a specific patient's care have legitimate access to the records. Many patients request copies of their health records, and they have the right to read their records. Each institution has policies for controlling the manner in which records are shared. In most situations, institutions are required to obtain written permission from patients to release medical information.

As a nurse, you are also responsible for protecting records from all unauthorized readers. When nurses and other health care providers have a legitimate reason to use records for data gathering, research, or continuing education, they must obtain appropriate authorization according to agency policy. Nursing students and faculty may be required to present identification indicating they are authorized to access records. The health care agency stores the records after the treatment ends.

Before the beginning of clinical placements, students and instructors may be required to sign confidentiality agreements with the agencies in question. Students need to understand the practice standards and laws concerning confidentiality. A breach of confidentiality is often a careless rather than a deliberate act. Students need to make sure that patient-identifiable

information (e.g., files, stickers, information in notebooks, worksheets) is not taken home and is disposed of correctly in a secure bin for shredding. Examples of breaches of confidentiality are accessing information not related to your duties, discussing patient information in an inappropriate area such as an elevator or on public transport, revealing to a caller confidential patient or co-worker details, e-mailing patient information through a public network such as the Internet, and leaving confidential material in a public area. Even after you are no longer on placement at an agency, you are obligated to maintain the confidentiality of patients and co-workers at that agency.

Personal Information Protection and Electronic Documents Act

The *Personal Information Protection and Electronic Documents Act* (PIPEDA) is federal legislation that protects personal information, including health information. PIPEDA delineates how private-sector organizations may collect, use, or disclose personal information in the course of commercial activities. Individuals have the right to access and request correction of any personal information collected about them as well. PIPEDA applies to all organizations engaged in commercial activities unless the federal government exempts an organization or activity in a province with similar legislation. PIPEDA is discussed in more detail in Chapter 16.

Multidisciplinary Communication Within the Health Care Team

Patient care requires effective communication among members of the health care team. Communication takes place through the patient's record or chart and reports.

A patient's **record**, or chart, is a confidential, permanent legal document of information relevant to a patient's health care. Information about the patient's health care is recorded after each contact with the patient. The record is a continuing account of the patient's health care status and is available to all members of the health care team. All health records contain the following information:

- Patient identification and demographic data
- Informed consent for treatment and procedures
- Advance directives
- Admission nursing history
- Nursing diagnoses or problems and the nursing or multidisciplinary care plan
- Record of nursing care treatment and evaluation
- Medical history
- Medical diagnosis
- Therapeutic orders
- Progress notes for various health care providers
- Reports of physical examinations
- Reports of diagnostic studies
- Record of patient and family education
- Summary of operative procedures
- Discharge plan and summary

Reports are oral, written, or audiotaped exchanges of information between caregivers. Reports commonly compiled by nurses include change-of-shift reports, telephone reports, transfer reports, and incident reports (see "Reporting" later in this chapter). A physician or nurse practitioner may call a nursing unit to receive a verbal report on a patient's condition

Figure 15-1 Staff communicate information about their patients during a change-of-shift report.

and progress. A laboratory submits a written report about the results of diagnostic tests.

Team members communicate information through discussions or conferences (Figure 15-1). For example, a discharge planning conference often involves members of several disciplines (e.g., nursing, social work, dietary, medicine, and physiotherapy), who meet to discuss the patient's progress toward established discharge goals. **Consultations** are another form of discussion whereby one professional caregiver gives formal advice about the care of a patient to another caregiver. For example, a nurse caring for a patient with a chronic wound may need a consultation with a wound care specialist. **Referrals** (an arrangement for services by another care provider), consultations, and conferences must be documented in a patient's permanent record so that all caregivers can plan care accordingly.

Purposes of Records

A record is a valuable source of data that is used by all members of the health care team. Its purposes include communication and care planning, legal documentation, education, funding and resource management, research, and auditing-monitoring.

Communication and Care Planning

The record is a means by which health care team members communicate patient needs and progress, individual therapies, content of conferences, patient education, and discharge planning. The plan of care needs to be clear to everyone reading the chart. The record should be the most current and accurate source of information about a patient's health care status.

In the record, always communicate the manner in which you conduct the nursing process with a patient. The admitting nursing history and physical assessment are comprehensive and provide baseline data about the patient's health status on admission to the facility. These data usually include biographical information (e.g., age and marital status), method of admission, reason for admission, a brief medical-surgical history (e.g., previous surgeries or illnesses), allergies, current medication (prescribed and over-the-counter), the patient's

perceptions about illness or hospitalization, and a review of health risk factors. Results of a physical assessment of all body systems are either documented in the nursing history or included on a separate form (see Chapter 31).

The medical progress notes should complement nursing process information. The notes detail the physician's or nurse practitioner's findings at the time of assessment. Nurses first refer to the patient's health care record for relevant assessment findings so that they can anticipate the patient's status and then conduct an individualized patient assessment.

The record provides data that you use to identify and support nursing diagnoses, establish expected outcomes of care, and plan and evaluate interventions. Information from the record adds to your observations and assessment. You do not need to collect information that is already available. If you have reason to believe that the information is inaccurate, information should be verified and appropriate changes made to the patient's record.

Legal Documentation

Accurate documentation is one of the best defences against legal claims associated with nursing care (see Chapter 8). From a legal perspective, the purpose of documentation is "always to accurately and completely record the care given to patients, as well as their response to that care" (Monarch, 2007, p. 58). According to Cartwright-Vanzant (2010, p. 134), the medical record is vital evidence in negligent practice lawsuits and considered as important as the testimony of witnesses in the courtroom. To limit nursing liability, you must clearly document that individualized, goal-directed nursing care, based on the nursing assessment, was provided to a patient and that you continue to monitor for, document, and report deterioration (Austin, 2008). The record must describe exactly what happened to a patient. Charting should be performed immediately after care is provided. Nursing care may have been excellent, but in a court of law, care not documented is care not provided (Graves Ferrell, 2007). When the chart is reviewed in court, it must show that the patient received "the best, most appropriate care possible" (Duclos-Miller, 2007). In the health care record, you need to indicate all assessments, interventions, patient responses, instructions, and referrals. It is important to complete all documentation on appropriate forms and to be sure that patient-identifying information (patient's name and identification number) is on every page of documentation.

The Nurses Service Organization (2011) (a medical malpractice, professional liability, and risk management company) identified eight common charting mistakes that can result in malpractice: (1) failing to record pertinent health or drug information, (2) failing to record nursing actions, (3) failing to record the administration of medications, (4) recording on the wrong chart, (5) failing to document a discontinued medication, (6) failing to record drug reactions or changes in the patient's condition, (7) transcribing orders improperly or transcribing improper orders, and (8) writing illegible or incomplete orders. Table 15-1 provides guidelines for legally sound documentation.

Education

A patient's record contains a variety of information, including diagnoses, signs and symptoms of disease, successful and unsuccessful therapies, diagnostic findings, and patient behaviours. By reading the patient care record, you can learn the nature of an illness and the patient's response to the illness.

TABLE 15-1 Legal Guidelines for Recording

Guidelines	Rationale	Correct Action
Do not erase, apply correction fluid to, or scratch out errors made while recording.	Charting becomes illegible: It may appear as if you were attempting to hide information or deface record.	Draw single line through error; write "error," "mistaken entry," "delete," or "void" above it; and sign your name or initials and date. Then record note correctly.
Do not write retaliatory or critical comments about patient or care by other health care providers.	Subjective statements can be used as evidence of nonprofessional behaviour or of poor quality of care.	Enter only objective descriptions of patient's behaviour; direct quotes from patient are preferred.
Correct all errors promptly.	Errors in recording can lead to errors in treatment or may imply an attempt to mislead or hide evidence.	Avoid rushing to complete charting; be sure that information is accurate.
Record all facts.	Record must be accurate, factual, and objective.	Be certain entry is factual and thorough; do not speculate or guess. A person reading the documentation should be able to determine that the patient was adequately cared for.
Chart as close as prudently possible to the time of the event.	This is the only accurate method of recalling details. Details can be lost and discrepancies can arise the longer the wait to the documentation of the event.	Document as soon after the event as possible to ensure accuracy.
Do not leave blank spaces in nurse's notes.	Another person can add incorrect information in spaces.	Chart consecutively, line by line; if space is left, draw line horizontally through it and sign your name at end.
Record all entries legibly and in black ink. Do not use felt-tip pens or erasable ink.	Illegible entries can be misinterpreted, thereby causing errors and lawsuits; felt-tip pen ink smudges or runs when wet and may destroy documentation; erasures are not permitted in patient charting. Black ink is more legible when records are photocopied or scanned.	Chart legibly in black ink; avoid the use of erasers, correction fluid, and pencils for documentation.
If an order is questioned, record that clarification was sought.	If you perform an order known to be incorrect, you are just as liable for prosecution as the prescriber is.	Do not record, "physician made error"; instead, chart that "Dr. Wong was called to clarify order for analgesic." Include the date and time of phone call, whom you spoke with, and the outcome.
Chart only your own actions.	You are accountable for information you enter into chart.	Never chart for someone else, except for the following situation: If caregiver has left unit for the day and calls with information that needs to be documented, include the date and time of entry, and reference the specific date and time you are referring to and the name of source of information in the entry, and include that the information was provided by telephone.
Avoid using generalized, empty phrases such as "status unchanged" or "had good day."	Such information is too generalized and has no meaning. Specific information about patient's condition is missing.	Use complete, concise descriptions of care so that documentation is objective and factual.
Begin each entry with the date and time, and end with your signature and title.	This guideline ensures that correct sequence of events is recorded; signature indicates who is accountable for care delivered.	Do not wait until end of shift to record important changes that occurred several hours earlier; be sure to sign each entry (e.g., Mei Lin, RN).
Avoid "precharting" (documenting an entry before performing a treatment or an assessment or before giving a medication).	Precharting invites error and thus endangers the health and safety of the patient; it is also illegal and can constitute falsification of health care records.	Document during or immediately after giving care or after administering a medication.
For computer documentation, keep your password to yourself.	This maintains security and confidentiality.	Once logged on to the computer, do not leave the computer screen unattended. Make sure the computer screen is not accessible for public viewing.

No two patients have identical records, but patterns of information can be identified in records of patients with similar health problems. With this information, you can identify patterns for various health problems and begin to anticipate the type of care required for a patient.

Funding and Resource Management

The patient care record shows how health care agencies have used their financial resources. Various tools help monitor the timing and reasons for health team–patient interactions. These data are then compared with documented entries on the chart to demonstrate the need for and efficacy of health care resources. In some workload assignment systems, health care interactions and tasks are assigned specified points in relation to time spent with each patient.

Research

Statistical data relating to the frequency of clinical disorders, complications, use of specific medical and nursing therapies, recovery from illness, and deaths can be gathered from patient records. For example, as part of a quality improvement program for patients receiving intravenous therapy, a nurse manager reviews patients' records to investigate the incidence of infection in patients with a specific type of intravenous catheter. This review reveals that the infection rate is increased, and the nurse manager and staff nurses design a new method for intravenous catheter care. Once this new intervention is implemented, the manager again reviews patients' records to determine whether the infection rate decreases.

A nurse may use patients' records during a clinical research study to investigate a new nursing intervention. For example, a nurse wants to compare a new method of pain control with a standard pain protocol, by using two groups of patients. The patient records provide data on the two types of interventions: the new method and the standard pain control. The nurse researcher collects data from the patients' records that describe the types and doses of analgesic medications used, objective assessment data, and patients' subjective reports of pain relief. The researcher then compares the findings to determine whether the new method was more effective.

Some data collection activities may be part of the quality improvement practices at an agency, whereas other activities may be actual clinical research studies. Different types of permission must be secured before a researcher can review patient records for any type of research study or data analysis. The researcher must be sure that the data collection and analysis adhere to provincial, territorial, and agency policies.

Auditing-Monitoring

A regular review of information in patient records helps you evaluate the quality and appropriateness of care. This audit may be either a review of care received by discharged patients or an evaluation of care currently being given. Most Canadian health care agencies have continuous quality improvement programs and teams to monitor and improve the delivery of health care services. These teams often contain members from across the organization, and they normally perform the self-assessment requirements of Accreditation Canada (see Chapter 10). Nurses or cross-discipline members of a committee monitor or review records throughout the year to determine the degree to which quality improvement standards are met. Deficiencies are explained to the nursing staff so that corrections in policy or practice can be made.

Guidelines for Quality Documentation and Reporting

High-quality documentation and reporting enhance efficient, individualized patient care and have the potential to improve patient outcomes. According to Jeffries et al. (2010), nursing documentation too often consists of a list of tasks performed, and the production of quality documentation can be a challenge for nurses. High-quality documentation and reporting have six important characteristics: they are factual, accurate, complete, current, and organized, and they comply with standards set by Accreditation Canada and by provincial or territorial regulatory bodies.

Factual

A factual record contains descriptive, objective information about what a nurse sees, hears, feels, and smells. An objective description is the result of direct observation and measurement: for example, "BP 80/50, patient diaphoretic, heart rate 102 and regular. L. Woo, RPN" (where "BP" stands for "blood pressure"). The use of inferences (e.g., "patient appears to be in shock") without supporting factual data is not acceptable because inferences can be misunderstood.

The use of vague terms, such as *appears*, *seems*, or *apparently*, is not acceptable because these words reflect opinion. For example, the description "the patient seems anxious" does not accurately communicate facts and does not inform another caregiver of the details regarding the behaviours exhibited by the patient that led to the use of the word *anxious*. The phrase *seems anxious* is a conclusion without supported facts. Objective documentation includes the observations of the patient's behaviours. For example, objective signs of anxiety can include increased pulse rate, increased respirations, and increased restlessness.

When recording subjective data, document the patient's exact words within quotation marks whenever possible (e.g., "Patient states, 'I feel very nervous and out of control'").

Accurate

The use of exact measurements establishes accuracy. For example, a description such as "Intake, 360 mL of water" is more accurate than "Patient drank an adequate amount of fluid." These measurements can later be used as a means to determine whether a patient's condition has changed. Charting that an abdominal wound is "5 cm in length without redness, drainage, or edema" is more descriptive than "large wound healing well."

Documentation of concise data should be clear and easy to understand. Avoid the use of unnecessary words and irrelevant detail. For example, the fact that the patient is watching TV is relevant only when this activity has relevance to the patient's status and plan of care.

Most health care institutions develop a list of standard abbreviations, symbols, and acronyms to be used by all members of the health care team in documenting or communicating patient care and treatment. Approved abbreviations and acronyms vary, depending on the type of facility (i.e., long-term versus acute care facility). Use of an institution's accepted abbreviations, symbols, and system of measures (e.g., metric) ensures that all staff members use the same language in their reports and records. Always use abbreviations carefully to avoid misinterpretation. For example, "od" (every day) can be misinterpreted to mean "O.D." (right eye). If

► **TABLE 15-2** Examples of Criteria for Reporting and Recording

Topic	Criteria to Report or Record
Assessment	
Subjective data	Description of episode in quotation marks; for example, "I feel as if I have an elephant sitting on my chest, and I can't catch my breath." Onset, location, description of condition (severity, duration, frequency; precipitating, aggravating, and relieving factors); for example, "The pain in my left knee started last week after I knelt on the ground. Every time I bend my knee, I have a shooting pain on the inside of my knee."
Patient behaviour (e.g., anxiety, confusion, hostility)	Onset, behaviours exhibited, precipitating factors, patient's verbal response; for example, "Patient observed pacing in her room, avoiding eye contact with nurse, and repeatedly stating, 'I have to go home now.'"
Objective data (e.g., rash, tenderness, breath sounds)	Onset, location, description of condition (see "Subjective data" above); for example, "1100 hrs: 2 cm raised pale red area noted on back of left hand."
Nursing Interventions and Evaluation	
Treatments (e.g., enema, bath, dressing change)	Time administered, equipment used (if appropriate), patient's response (objective and subjective changes) in comparison with previous treatment; for example, "Patient denied pain during abdominal dressing change" or "Patient reported severe abdominal cramping during enema."
Medication administration	Immediately after administration, document time when medication is given, preliminary assessment (e.g., pain level, vital signs), patient response or effect of medication; for example, "1500: Patient reports a 'throbbing headache all over her head.' Rates pain as 6 (scale 0–10). Tylenol 650 mg given PO. 1530: Patient reports pain level 2 (scale 0–10) and states 'the throbbing has stopped.'"
Patient teaching	Information presented, method of instruction (e.g., discussion, demonstration, videotape, booklet), and patient response, including questions and evidence of understanding such as demonstration of correct self-care or change in behaviour.
Discharge planning	Measurable patient goals or expected outcomes, progress toward goals, need for referrals.

abbreviations are confusing, then to minimize errors, you should spell them out in their entirety.

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) published a minimum list of dangerous abbreviations that should no longer be used in written medical documentation. Suggestions include writing "unit" instead of "U"; always using a zero before a decimal point in a decimal fraction (e.g., "0.25 mg"); and not writing a zero alone after a decimal point (e.g., writing "5 mg," not "5.0 mg"). The Institute for Safe Medication Practices (2010) published a more extensive list of error-prone abbreviations, symbols, and dose designations that health care institutions also need to consider adding to their "Do Not Use" lists (see Chapter 33).

Correct spelling demonstrates a level of competency and attention to detail. Many terms can easily be misinterpreted (e.g., *dysphagia* and *dysphasia*). Some spelling errors can also result in serious treatment errors; for example, the names of certain medications, such as *digitoxin* and *digoxin* or *morphine* and *hydromorphone*, are similar and must be transcribed carefully to ensure that the patient receives the correct medication.

Record entries must be dated, and a method for identifying the authors of entries must be in place. Therefore, each entry in a patient's record ends with the caregiver's full name or initials and status, such as "Holly Lee, RPN." Each time initials are used, the full name and status must previously appear on the same page so that the individual entering initials can be readily identified. A nursing student enters full name, student nurse abbreviation (e.g., "SN" or "NS"), and educational institution: for example, "Henri Gauthier, SN 1 [student nurse, year one], U of S [University of Saskatchewan]."

Records must reflect accountability during the time frame of the entry. Accountability is best accomplished when you chart only your own observations and actions. Your signature holds you accountable for information recorded. If information was inadvertently omitted from the record, it is acceptable for you to ask colleagues to chart information on your behalf after you leave work. The entry needs to clearly show what was done and by whom (e.g., "At 1100 hrs, Sam Roustas, RN, called and reported that at 0800 hrs, morphine sulphate, 5 mg subcutaneous, was administered to patient for abdominal pain. F. Khan, R.N.").

You should refer to agency policy before making late entries, correcting errors, or completing an omission. Late entries are often documented by writing the current date and time in the next available space as close to the late entry as possible and writing "late entry for [date and shift]." For adding information to an existing entry, using the current date and time in the next space and adding "addendum to note of [date and time of prior note]" is a good practice.

Complete

The information within a recorded entry or a report must be complete, containing appropriate and essential information. Criteria for thorough communication exist for certain health problems or nursing activities (Table 15-2). It is important to document all nursing interventions, such as education and psychosocial support, as this information and the outcomes of these interventions are not often recorded in nursing documentation (Jeffries et al., 2010). An example of a thorough nurse's note is as follows:

"1915: Patient verbalizes sharp, throbbing pain localized along lateral side of right ankle, beginning approximately 15 minutes after twisting

his foot on the stairs at 1700. Patient rates pain as 8 on a scale of 0–10. Pain increased with movement, slightly relieved with elevation. Pedal pulses equal bilaterally. Right ankle circumference 2 cm larger than left. Capillary refill less than 3 seconds bilaterally. Right foot: warm to touch and pale pink, skin intact. Patient able to move toes and respond to tactile stimulation on right foot. Ice applied. Percocet 2 tabs (PO) given for pain. Patient states pain somewhat relieved with ice, rates pain as 6 on a scale of 0–10. Dr. P. Yoshida notified. Lee Turno, RN."

Current

Timely entries are essential to the patient's ongoing care. Documentation should occur during or as soon as possible after the incident or intervention, and events should be described chronologically to reflect a clear record of exactly what happened (College of Nurses of Ontario, 2009). To increase accuracy and decrease unnecessary duplication, many health care agencies use bedside records, which facilitate immediate documentation of information as it is collected from a patient.

Flow sheets (described later in this chapter) are a means of entering current information quickly. Portable electronic workstations or secure wall cabinets in patient rooms help ensure that patient confidentiality is maintained. Nurses often keep notes on a worksheet when caring for several patients, making notes as the care occurs to ensure that entries recorded later in the record are accurate. The following activities and findings should be communicated at the time of occurrence:

- Vital signs
- Administration of medications and treatments
- Preparation for diagnostic tests or surgery
- Change in patient's status and who was notified (e.g., nurse practitioner, physician, manager, patient's family)
- Admission, transfer, discharge, or death of a patient
- Treatment for a sudden change in patient's status
- Patient's response to treatment or intervention

Health care agencies use military time, a 24-hour system that avoids misinterpretation of "A.M." and "P.M." times (Figure 15-2). Instead of two 12-hour cycles in standard time,

the military clock is one 24-hour time cycle. The military clock ends with midnight (2400) and begins with 1 minute after midnight (0001). For example, 10:22 A.M. is 1022 military time; 1:00 P.M. is 1300 military time.

Organized

As a nurse, you want to communicate information in a logical order. For example, an organized note describes the patient's pain, the nurse's assessment and interventions, and the patient's response. To write notes about complex situations in an organized manner, think about the situation and make notes of what is to be included before you begin to write in the permanent legal record.

Compliant With Standards

Documentation needs to follow standards set by Accreditation Canada and by provincial or territorial regulatory bodies to maintain institutional accreditation and to decrease the risk of liability. Current standards require that all patients who are admitted to a health care institution undergo physical, psychosocial, environmental, and self-care assessments; receive patient education; and be provided discharge planning. In addition, criteria for standards stress the importance of evaluating patient outcomes, including the patient's response to treatments, teaching, or preventive care.

The nursing service department of each health care agency selects a method of documenting patient care. The method reflects the philosophy of the nursing department and incorporates the standards of care. Because the nursing process shapes a nurse's approach and direction of care, effective documentation also reflects the nursing process.

Common Documentation Systems

Patient data can be recorded in several documentation systems. Each nursing service selects a documentation system that reflects the philosophy of its department. The same documentation system is used throughout a specific agency and may also be used throughout a health care system.

Narrative Documentation

Narrative documentation is the traditional method for recording nursing care. It is simply the use of a story-like format to document information specific to patient conditions and nursing care. Narrative charting, however, has many disadvantages, including the tendency to have repetitious information, to be time consuming to complete, and to require the reader to sort through much information to locate desired data.

Problem-Oriented Medical Records or Health Care Records

The **problem-oriented medical record** is a method of documentation that emphasizes the patient's problems. Data are organized by problem or diagnosis. Ideally, each member of the health care team contributes to a single list of identified patient problems. This assists in coordinating a common plan of care. The problem-oriented medical record has the following major sections: database, problem list, care plan, and progress notes.

Database. The database section contains all available assessment information pertaining to the patient (e.g., history and physical examination findings, the nurse's admission history and ongoing assessment, the dietitian's assessment,

Figure 15-2 Military time clock.

laboratory reports). The database is the foundation for identifying patient problems and planning care. As new data become available, you revise the database. The database accompanies patients through successive hospitalizations or clinic visits.

Problem List. After analyzing data, health care team members identify problems and make a single problem list. The problems include the patient's physiological, psychological, social, cultural, spiritual, developmental, and environmental needs. Team members list the problems in chronological order and file the list in the front of the patient's record to serve as an organizing guide for the patient's care. You add new problems as they are identified. When a problem has been resolved, you record the date of resolution, and highlight the date or draw a line through the problem and its number.

Care Plan. A care plan is developed for each problem by the members of the health care team from each discipline involved in the patient's care. Nurses document the plan of care in a variety of formats. In general, these plans of care include nursing diagnoses, expected outcomes, and interventions.

Progress Notes. Health care team members monitor and record the progress of a patient's problems (Box 15-1). The information can be expressed in various formats. One method

is the **subjective-objective-assessment-plan (SOAP)** charting, involving subjective data (verbalizations of the patient), objective data (data that are measured and observed), assessment (diagnosis based on the data), and plan (what the caregiver plans to do). Some institutions add intervention (I) and evaluation (E) (i.e., **subjective-objective-assessment-plan-intervention-evaluation [SOAPIE]**). The logic for SOAP and SOAPIE notes is similar to that of the nursing process: to collect data about the patient's problems, draw conclusions, and develop a plan of care. The nurse numbers each SOAP or SOAPIE note and titles it according to the problem on the list.

A second progress note method is the **problem-intervention-evaluation (PIE)** format (see Box 15-1). It is similar to SOAP charting in its problem-oriented nature. However, it differs from the SOAP method in that PIE charting originated in nursing practice, whereas SOAP charting originated from medical records. The PIE format simplifies documentation by unifying the care plan and progress notes. PIE notes differ from SOAP notes because the narrative does not include assessment information. A nurse's daily assessment data appear on flow sheets, preventing duplication of data. The narrative note includes the problem, the intervention, and the evaluation. The PIE notes are numbered or labelled according to the patient's problems. Resolved problems are dropped from daily documentation after the nurse's review. Continuing problems are documented daily.

A third progress note format is **focus charting**. It involves use of **data-action-response (DAR)** notes, which include both subjective and objective data, the action or nursing intervention, and the response of the patient (i.e., evaluation of effectiveness). One distinction of focus charting is its movement away from charting only problems, which has a negative connotation. Instead, a DAR note addresses patient concerns: a sign or symptom, a condition, a nursing diagnosis, a behaviour, a significant event, or a change in a patient's condition. Documentation is written in accordance with the nursing process; nurses are encouraged to broaden their thinking to include any patient concerns, not just problem areas; and critical thinking is encouraged. The benefits of focus charting are that it incorporates all aspects of the nursing process, highlights the patient's concerns, and can be integrated into any clinical setting (*Mosby's Surefire Documentation*, 2006).

➤ BOX 15-1

Examples of Progress Notes Written in Different Formats

Subjective-Objective-Assessment-Plan (SOAP)

01/19/11 Knowledge deficit regarding surgery at 1630 hrs related to inexperience

S: "I'm worried about what it will be like after surgery."

O: Patient asking frequent questions about surgery. Has had no previous experience with surgery. Wife present and acting as a support person.

A: Knowledge deficit regarding surgery related to inexperience. Patient also expressing anxiety.

P: Explain routine preoperative preparation. Demonstrate and explain rationale for turning, coughing, and deep breathing (TCDB) exercises. Provide explanation and teaching booklet on postoperative nursing care. S. Lazarus, RPN

Problem-Intervention-Evaluation (PIE)

P: Knowledge deficit regarding surgery related to inexperience.

I: Explained normal preoperative preparations for surgery to patient. Demonstrated TCDB exercises. Provided booklet on postoperative nursing care to patient.

E: Patient demonstrates TCDB exercises correctly. Needs review of postoperative nursing care. S. Lazarus, RPN

Focus Charting: Data-Action-Response (DAR)*

D: Patient stating, "I'm worried about what it will be like after surgery." Patient asking frequent questions about surgery. Has had no previous experience with surgery. Wife present; acts as a support person.

A: Explained normal preoperative preparations for surgery to patient. Demonstrated TCDB exercises. Provided booklet on postoperative nursing care to patient.

R: Patient demonstrates TCDB exercises correctly. Needs review of postoperative nursing care. Patient states, "I feel better knowing a little bit of what to expect." S. Lazarus, RPN

*Some agencies also add P (Plan) to make DARP.

Source Records

In a **source record**, the patient's chart is organized so that each discipline (e.g., nursing, medicine, social work, respiratory therapy) has a separate section in which to record data. One advantage of a source record is that caregivers can easily locate the proper section of the record in which to make entries. Table 15-3 lists the components of a source record.

A disadvantage of the source record is that details about a specific problem may be distributed throughout the record. For example, in the case of a patient with bowel obstruction, the nurse describes in the nurses' notes the character of abdominal pain and the use of relaxation therapy and analgesic medication. In a separate section of the record, the physician's notes describe the progress of the patient's condition and the plan for surgery. The findings of X-ray examinations that reveal the location of the bowel obstruction are in the test results section of the record.

The nursing notes or progress notes section is where nurses enter a narrative description of nursing care and the patient's response (Box 15-2). It is also a section for documenting care

► **TABLE 15-3** Organization of Traditional Source Record

Sections	Contents
Admission sheet	Specific demographic data about patient: legal name, identification number, sex, age, birth date, marital status, occupation and employer, health card number, nearest relative to notify in an emergency, religious affiliation, name of attending physician, date and time of admission
Order sheet	Record of physician's or nurse practitioner's orders for treatment and medications, with date, time, and physician's signature
Nurse's admission assessment	Summary of nursing history and physical examination
Graphic sheet and flow sheet	Record of repeated observations and measurements such as vital signs, daily weights, and intake and output
Medical history and examination	Results of initial examination performed by physician, including findings, family history, confirmed diagnoses, and medical plan of care
Medication administration record (MAR)	Accurate documentation of all medications administered to patient: date, time, dose, route, and nurse's signature
Progress notes	Ongoing record of patient's progress and response to therapy completed by all members of the health care team. Included in this section is a narrative record of the nursing process written by nurses: assessment, nursing diagnosis, planning, implementation, and evaluation of care
Health care disciplines' records	Entries made into record by all health care-related disciplines: radiology, social work, laboratories, physiotherapy, and so forth
Discharge summary	Summary of patient's condition, progress, prognosis, rehabilitation, and teaching needs at time of dismissal from hospital or health care agency

► **BOX 15-2** Sample Narrative Note

04/03/11

1100 hrs: Patient states, "I'm having a hard time catching my breath." R [Respirations], laboured at 32/min; P [pulse] 120; BP 112/70. Oxygen saturation 90% on room air. Patient alert and oriented. Patient using intercostal muscles during inspiration. Wheezes noted in both lower lobes. Chest excursion equal bilaterally. Elevated head of bed to Fowler's position. Obtained arterial blood gas (ABG) sample at 1045. O₂ started at 2 L/min per nasal prongs as ordered. Remained at bedside to calm patient. P. Haske, RN

1130 hrs: Results of ABGs reported to Dr Stein are pH 7.34; PCO₂ [partial pressure of carbon dioxide] 44 mm Hg; PO₂ [partial pressure of oxygen] 80 mm Hg.

Patient states, "It is easier to breathe now." R 24/min; P 96; BP 110/72. Oxygen saturation 97% on O₂ at 2 L/min per nasal prongs, lips pale pink; capillary refill less than 3 seconds. Wheezing still audible on auscultation. Patient remains in high Fowler's position. P. Haske, RN

that is provided by the physician or nurse practitioner in the nurse's presence. The nurse may record key diagnostic test results from other sections of the record in the nurses' notes if they are of major importance in the care of the patient.

Charting by Exception

Charting by exception (CBE) focuses on documenting deviations from the established norm or abnormal findings. This approach reduces documentation time and highlights trends or changes in the patient's condition (*Mosby's Surefire Documentation*, 2006). It is a shorthand method for documenting normal findings and routine care on the basis of clearly defined standards of practice and predetermined criteria for nursing assessments and interventions. Clearly defined standards of practice that specify nurses' responsibilities to patients provide

the framework for routine care of all patients. With standards integrated into documentation forms, such as predefined normal assessment findings or predetermined interventions, you only need to document significant findings or exceptions to the predefined norms. In other words, you write a progress note only when the standardized statement on the form is not met. Assessments are standardized on flow sheets or other forms so that all caregivers evaluate and document findings consistently (Figure 15-3).

Because the standard assessments are located in the chart, patient data are already present on the permanent record, and so you do not need to keep temporary notes for later transcription, and caregivers have easy access to current data. The assumption with CBE is that all standards are met unless otherwise documented.

When you see entries in the chart, you know that something out of the ordinary has been observed or has occurred. For that reason, when changes in a patient's condition have developed, it is easy to track them.

When patients' conditions change, it is essential to describe thoroughly and precisely what happens to patients and the actions taken. CBE can pose legal risks if nurses are not diligent in documenting exceptions. This charting method fails to provide a thorough picture of a patient's developing condition and does not reflect communication among members of the health care team (*Mosby's Surefire Documentation*, 2006). If nurses rely too heavily on charting standard categories and do not enter exception notes, the patient's situation will not be clear. CBE can also be problematic when related documentation forms do not have space allotted for documenting patient and family perspectives.

Case Management Plan and Critical Pathways or Care Maps

The **case management** model of delivering care (see Chapter 10) incorporates a multidisciplinary approach to documenting patient care. In many organizations, the standardized plan of

CAST SITE Assessment _____ Damp _____		Cast dry and intact; nil-minimal drainage; sensation normal; swelling nil-minimal. Damp 24-48 hours.												

Figure 15-3, cont'd

care is summarized into critical pathways for a specific disease or condition. The **critical pathways** or **care maps** are multidisciplinary care plans that include patient health concerns, key interventions, and expected outcomes within an established time frame (Figure 15-4). In a computerized charting system, professionals from many disciplines may access the chart, and this integration of information from the different disciplines can be accessed easily from every computer terminal in the institution at any time. The nurse and other team members such as physicians, nurse practitioners, dietitians, social workers, physiotherapists, and respiratory therapists use the same critical pathway to monitor the patient's progress during each shift or, in the case of home care, during every visit.

Critical pathways eliminate the need for nurses' notes, flow sheets, and nursing care plans because the pathway document integrates all relevant information. Unexpected occurrences, unmet goals, and interventions not specified within the clinical pathway time frame are called **variances**. A variance is present when the activities on the clinical pathway are not completed as predicted or the patient does not meet the expected outcomes. An example of a negative variance is when a patient postoperatively develops pulmonary complications necessitating oxygen therapy and monitoring with pulse oximetry. An example of a positive variance is when a patient progresses more rapidly than expected (e.g., use of a Foley catheter may be discontinued a day early). A variance analysis is necessary to review the data for trends and for developing and implementing an action plan to respond to the identified patient problems (Box 15-3). In addition, variances may result from changes in the patient's health or may occur as a result of other health complications not associated with the primary reason why the patient requires care. Once a variance has been identified, the nurse modifies the patient's care to meet the needs associated with the variance.

Consensus on the definition and impact of critical pathways is lacking. The pathways were developed to improve the efficiency of care in hospitals and as a cost containment measure to reduce length of hospital stay. According to Dy and colleagues (2005), critical pathways may be effective only under certain circumstances (e.g., first pathway implemented in a particular practice area or for lesser severity of illness).

► BOX 15-3

Example of Variance Documentation

A 56-year-old patient is on a surgical unit one day after a bowel resection. His temperature is slightly elevated, his breath sounds are decreased bilaterally at both lung bases, and he is slightly confused. Ordinarily, one day postoperatively, a patient should be afebrile with clear lungs. The following is an example of the variance documentation for this patient.

9/23/10

1000 hrs: Breath sounds diminished bilaterally at the bases. T [temperature] 37.8°C; P 92; R 28/min; oxygen saturation 84%. Daughter states he is "confused" and did not recognize her when she arrived a few minutes ago. Oxygen started at 2 L/min via nasal prongs. Head of bed elevated. Will monitor oxygen saturation and vital signs every 15 minutes. Dr. P. Yoshida notified of change in status. Daughter at bedside. R. Balliol, RN

Common Record-Keeping Forms

A variety of forms are specially designed for the type of information that nurses routinely document. The categories within a form are usually derived from institutional standards of practice or guidelines established by accrediting agencies.

Admission Nursing History Forms

A nursing history form is completed when a patient is admitted to a nursing care unit. The history form guides the nurse through a complete assessment to identify relevant nursing diagnoses or problems (see Chapter 12). Data on history forms provide baselines that can be compared with changes in the patient's condition.

Flow Sheets and Graphic Records

Flow sheets are forms in which nurses can quickly and easily enter assessment data about the patient, including vital sign measurements and routine repetitive care actions, such as hygiene measures, ambulation, meals, weights, and safety and restraint checks (Box 15-4). The format of the flow sheet varies in accordance with the agency and the data being recorded. For example, some flow sheets may be used only to record vital sign measurements (often called *graphic records*); others may be more comprehensive (Figure 15-5; note that Figure 15-3 shows a flow sheet that is used for CBE). For flow sheets, a coding system is used for data entry. It is important to fill out all spaces on the flow sheet, even for items that are "not applicable" (for which you can write "N/A"). A blank space can raise doubts about whether an intervention was or was not performed. If an occurrence recorded on the flow sheet is unusual or changes significantly, a focus note is needed (see Box 15-3). For example, if a patient's blood pressure becomes dangerously high, the nurse completes a focus assessment and records the findings, as well as action taken, in the progress notes. Flow sheets provide a quick, easy reference for the health care team members in assessing a patient's status. Critical care and acute care units commonly use flow sheets for all types of physiological data.

Patient Care Summary or Kardex

Many agencies now have computerized systems that provide basic, summative information in the form of a patient care summary. This is printed out for each patient during each shift. This summary is continually updated and provides the nurse with a current detailed list of orders, treatment, and diagnostic testing. In some settings, a **Kardex** system, a portable "flip-over" file or binder, is kept at the nurses' station. Most Kardex forms have an activity and treatment section and a nursing care plan section that organize information for quick reference as nurses give change-of-shift reports or make walking rounds. An updated Kardex form eliminates the need for repeated referral to the chart or computer record for routine information

Text continued on p. 219

► BOX 15-4

Benefits of Using a Flow Sheet

- Information is accessible to all members of the health care team.
- Time spent on writing a narrative note is decreased.
- Information is current.
- Errors resulting from transfer of information are decreased.
- Team members can quickly see trends over time.

throughout the day. In many institutions, entries on Kardex forms are made in pencil because of the need for frequent revisions as the patient's needs change. In settings in which the Kardex form is a permanent part of the patient's record, entries are made in ink. Information commonly found on the patient care summary or Kardex form includes the following:

- Basic demographic data (e.g., age, sex, religious affiliation)
- Hospital identification number
- Physician's name
- Primary medical diagnosis
- Medical and surgical history
- Current physician's or nurse practitioner's treatment orders to be carried out by the nurse (e.g., dressing changes, ambulation, glucose monitoring)
- Nursing care plan
- Nursing orders (e.g., education sessions, symptom relief measures, counselling)
- Scheduled tests and procedures
- Safety precautions to be used in the patient's care
- Factors related to activities of daily living
- Contact information about nearest relative or guardian or person to contact in an emergency
- Emergency code status
- Allergies

Acuity Records or Workload Measurement Systems

Acuity records (also known as **workload measurement systems**) provide a method of determining the hours of care and staff required for a given group of patients. A patient's *acuity level* is based on the type and number of nursing interventions required for providing care in a 24-hour period. The acuity level determined by the nursing care allows patients to be rated in comparison with one another. For example, an acuity system might rate bathing patients from 1 to 5 (1 means patient is totally dependent on others for bathing, 5 means patient bathes independently). A patient who has just undergone surgery and who requires frequent monitoring and extensive care may be listed with an acuity level of 1. On the same continuum, another patient awaiting discharge after a successful recovery from surgery has an acuity level of 5. Accurate acuity ratings may also be used to justify overtime and the number and qualifications of staff needed to safely care for patients. The patient-to-staff ratios established for a unit depend on a composite gathering of data for the 24-hour interventions that are necessary for each patient receiving care.

Standardized Care Plans

Some institutions use **standardized care plans** to make documentation easier for nurses. The plans, based on the institution's standards of nursing practice, are preprinted, established guidelines that are used to care for patients who have similar health problems. After a nursing assessment is completed, the staff nurse identifies the standard care plans that are appropriate for the patient. The care plans are placed in the patient's health care record. The standardized plans can be modified (and changes are noted in ink) to individualize the therapies. Most standardized care plans also allow the nurse to write in specific goals or desired outcomes of care and the dates by which these outcomes should be achieved.

One advantage of standardized care plans is establishment of clinically sound standards of care for similar groups of

► BOX 15-5 Discharge Summary Information

- Use clear, concise descriptions in patient's own language.
- Provide step-by-step description of how to perform a procedure (e.g., home medication administration). Reinforce explanation with printed instructions.
- Identify precautions to follow when the patient performs self-care or administers medications.
- Review signs and symptoms of complications that should be reported to the primary care practitioner.
- List names and phone numbers of health care providers and community resources that the patient can contact.
- Identify any unresolved problem, including plans for follow-up and continuous treatment.
- List actual time of discharge, mode of transportation, and who accompanied the patient.

patients. These standards can be useful when quality improvement audits are conducted. These care plans can help nurses recognize the accepted requirements of care for patients and also improve continuity of care.

The use of standardized care plans is controversial. The major disadvantage is the risk that the standardized plans prevent nurses from providing unique, individualized therapies for patients. Standardized care plans cannot replace the nurse's professional judgement and decision making. In addition, care plans need to be updated on a regular basis to ensure that content is current and appropriate.

Discharge Summary Forms

It is important to prepare patients for an efficient, timely discharge from a health care facility. A patient's discharge should also result in desirable outcomes. Multidisciplinary involvement in discharge planning helps ensure that a patient leaves the hospital in a timely manner with the necessary resources in place (Box 15-5).

Ideally, discharge planning begins at admission. You need to revise the care plan as the patient's condition changes. Remember to involve the patient and family members in the discharge planning process so that they have the information needed to return the patient home. Discharge information and instructions should include data such as the following:

- Instruction about potential food–drug interactions, nutrition intervention, and modified diets
- Rehabilitation techniques to support adaptation to, or functional independence in, the environment, or both
- Access to available community resources
- Circumstances in which patients should obtain further treatment or follow-up care
- Methods of obtaining follow-up care
- The patient's and family's responsibilities in the patient's care
- Medication instructions, including the times and reasons to take each medication, the dose, the route, precautions, possible adverse reactions, and information about when and how to get prescriptions refilled

Furthermore, a common standard in nursing practice is to educate patients about the nature of their disease process, its likely progress, and the signs and symptoms of complications.

When a patient is discharged from inpatient care, a discharge summary that includes information from members of the health care team is prepared. The summary is given to the patient or family or to the home care, rehabilitation, or long-term care agency. Discharge summary forms help make the summary concise and instructive (Figure 15-6). A summary form emphasizes previous learning by the patient and family and care that should be continued in any restorative care setting. When given directly to patients, the form may be attached to pamphlets or teaching brochures.

Home Health Care Documentation

As a result of shorter hospitalizations and larger numbers of older adults who require home care services, home health care is expanding. Because patients are leaving acute care settings earlier, increasing numbers of home care patients are presenting in the community setting with more acuity (i.e., sicker). The focus in home health care is on family-centred care and forming a partnership or collaboration with the patient and the family to help the patient regain health, to help the family take over the patient's care, or to help accomplish both. Documentation in the home health care system has different implications than in other areas of nursing. Two primary differences are that the majority of the care is performed by the patient and family and that the nurse is often teaching and helping the patient and family achieve greater independence. Nurses must have astute assessment skills to gather the needed information about changes in the patient's health care status. In addition, documentation systems need to provide the entire health care team with the information needed for them to work together effectively (Box 15-6).

In the home care setting, the patient is the guardian of the health care record. A hard copy of the health care record is kept in the patient's home, and the patient is responsible for its safekeeping. Communication is crucial in home care because much of the interaction between health care providers is conducted virtually by phone or fax over password-protected voice mail or secure fax lines. With the increasing availability of hand-held devices such as **personal digital assistants**

(PDAs), smart phones, and laptop computers or tablets, records can be available in multiple locations, which enables easier access to the multidisciplinary needs that are often associated with home care. Privacy remains a unique challenge in home health care, however, inasmuch as not all member of the health care team have access to secure electronic transmission of confidential material (e.g., as is the case in physicians' offices).

Long-Term Health Care Documentation

An increasing number of older adults require care in long-term care or residential facilities. Many individuals live in this setting for the rest of their lives and are therefore referred to as **residents** rather than as *patients*. In long-term care settings, nursing personnel face challenges much different from those in acute care settings. Residents' health is often stable, and so daily documentation can be completed on flow sheets. Assessments performed several times a day in acute care settings are required only weekly or monthly in long-term care settings.

Governmental agencies and provincial and territorial laws are instrumental in determining the standards and policies for documentation. Documentation is used to review the levels of care given to and needed by residents in long-term care facilities. Although most long-term care facilities have different documentation systems, these systems are based on the need for a concise, nonduplicating method of documentation and on the importance of nursing documentation in support of evidence-informed practice (Box 15-7).

Computerized Documentation

Many hospitals are using computerized documentation systems or are in the process of transitioning to computerized charting. Current software programs enable nurses to quickly enter specific assessment data, fill in forms with typical entry choices, and enter narrative for unique situations; computer memory is also adequate for large amounts of data, and

► BOX 15-6

Home Care Forms for Documentation

The usual forms used to document home care include the following:

- Assessment forms
- Referral source information or intake form
- Discipline-specific care plans
- Physician's plan of treatment
- Professional order form (e.g., MD, speech language pathologist, specialty nurses)
- Medication administration record
- Clinical progress notes
- Miscellaneous (case conference notes, professional communication forms, private billing forms, insurance company forms)
- Discharge summary

Adapted from Iyer, P. W., & Camp, N. H. (1999). *Nursing documentation: A nursing process approach*. St Louis, MO: Mosby.

► BOX 15-7

Components of Documentation in Long-Term Care

Section 1: The Health Care Record

The health care record includes the resident's name and medical number; date and time of admission; change in resident's condition; informed consent; note or discharge summary; incident reporting; monthly summary charting; and type of therapy and treatment time.

Section 2: Resident Assessments and Related Documents

This section consists of the admission record; preadmission assessment; admission assessment; assessment of risk for falls; skin assessment; bowel and bladder assessment; physical restraint assessment; record of self-administration of medication; nutrition assessment; and activities, recreation, or leisure interests.

Section 3: Other Records

Other records include drug therapy records, medication or treatment records, flow sheets or other graphic records, laboratory and special reports, consent forms, acknowledgements and notices, advance directives, and discharge or transfer records.

information can be automatically transferred to different reports. Computers can also help generate nursing care plans and document all facets of patient care.

Hand-held devices such as personal digital assistants also have the potential to increase nursing productivity by providing access to clinical and reference material, providing a means for decreasing medication errors, and reducing documentation time (Scordo et al., 2003). Nurses can document at the patient's bedside—at the point of care. **Point-of-care information systems** consist of hand-held devices such as personal digital assistants or computers that nurses bring to the patient's bedside.

Nursing Information Systems

A good information system supports the work you do. As a nurse, you need to be able to easily access a computer program, review the patient's medical history and new orders, and then go to the patient's bedside to conduct a comprehensive assessment. Once you have completed the assessment, you enter data into the computer terminal at the patient's bedside and develop a plan of care from the information gathered. Periodically, you will return to the computer to check on laboratory test results and document the therapies you administer. The computer screens and optional pop-up windows make it easy to locate information, enter and compare data, and make changes.

Nursing information systems have two basic designs. The nursing process design is the most traditional. It organizes documentation within well-established formats, such as admission and postoperative assessment, problem lists, care plans, discharge planning instructions, and intervention lists or notes. The nursing process design also includes formats for the following tasks:

- Generation of a nursing worklist that indicates routine scheduled activities related to the care of each patient
- Documentation of routine aspects of patient care, such as hygiene, positioning, fluid intake and output, wound care measures, and blood glucose measurements
- Progress note entries with the use of narrative notes, CBE, and flow sheet charting
- Documentation of medication administration

The second design model for a nursing information system is the protocol, or critical pathway, design (Hebda et al., 2005). This design offers a multidisciplinary format to managing information. All health care providers use a protocol system to document the care that they provide patients. Evidence-informed clinical protocols or critical pathways provide the formatting or design for the type of information that clinicians enter into the system. The information system allows a user to select one or more appropriate protocols for a patient. An advanced system merges multiple protocols so that a master protocol, or path, is used to direct patient care activities. The system identifies variances of the anticipated outcomes on the protocols as they are charted. This system provides all caregivers the ability to analyze variances and to obtain an accurate clinical picture of the patient's progress.

Advantages of a Nursing Information System. Few formal well-designed studies have demonstrated the impact of computerized record systems on nursing practice or patient outcomes. Anecdotal reports and descriptive studies suggest that nursing information systems do offer important advantages to nurses in practice. Hebda et al. (2005) outlined some specific advantages of nursing information systems:

- Increased time to spend with patients
- Better access to information
- Enhanced quality of documentation
- Reduced numbers of errors of omission
- Reduced hospital costs
- Increased nurse job satisfaction
- Enhanced compliance with accreditation standards
- Development of a common clinical database

Security Mechanisms. Computerized documentation has legal risks. Any given person could theoretically access a computer station within a health care agency and obtain information about almost any patient. Protection of privacy of information in computer systems is a top priority. As described in Chapter 16, Canada has both provincial and national privacy legislation to protect personal health information in electronic or other form.

In most security mechanisms for information systems, a combination of logical and physical restrictions is used to protect information and computer systems. These measures include the installation of firewalls, antivirus software, and spyware-detection software. A firewall is a combination of hardware and software that protects private network resources (e.g., a hospital's information system) from outside hackers, network damage, and theft or misuse of information. An example of a logical restriction is an automatic sign-off, a mechanism that logs a user off the computer system after a specified period of inactivity on the computer (Hebda et al., 2005).

Physical security measures include the placement of computers or file servers in restricted areas. This form of security may have limited benefit, especially if an organization uses mobile wireless devices such as notebooks, tablet personal computers, or personal digital assistants. Such devices can be easily misplaced or lost, which allows them to be accessed by unauthorized persons. An organization may use motion detectors or alarms with devices to help prevent theft.

One method of authenticating access to automated records is the use of access codes and passwords. A password is a collection of alphanumeric characters that a user types into the computer before he or she can access a program. A user is usually required to enter a password after the entry and acceptance of an access code or user name. A password does not appear on the computer screen when it is typed, nor should it be known to anyone but the user and information systems administrators (Hebda et al., 2005). Efficacious passwords contain combinations of letters, numbers, and symbols that are not easily guessed. When using a health care agency computer system, you must not share your computer password, under any circumstances, with anyone. A secure system requires frequent and random changes in personal passwords to prevent unauthorized persons from tampering with records. In addition, most staff members have access to patients in their work area only. Select staff members (e.g., administrators or risk managers) may be given authority to access all patient records.

Handling and Disposal of Information. It is important to keep medical records confidential, but it is equally important to safeguard the information that is printed from the record or extracted for report purposes. For example, you print a copy of a nursing activities worklist to use as a day planner while administering care to patients. You refer to information on the list and handwrite notes to enter later into the computer. Information on the list is considered to be personal health information and must be kept confidential and not left out for

view by unauthorized persons. You must destroy anything that is printed when the printed information is no longer needed.

All papers containing personal health information (e.g., patient's health care number, date of birth, age, name, or address) must be destroyed if they are not part of the patient's health record. Most agencies have shredders or locked receptacles for shredding and later incineration. Be sure you familiarize yourself with the disposal policies for records in the institution where you work.

Clinical Information Systems

Any clinician, including nurses, physicians, pharmacists, social workers, and therapists, will use programs available on a clinical information system. These programs include monitoring systems; order entry systems; and laboratory, radiology, and pharmacy systems. A monitoring system includes devices that automatically monitor and record biometric measurements (e.g., vital signs, oxygen saturation, cardiac index, and stroke volume) in critical care areas and specialty areas. The devices electronically send measurements directly to the nursing documentation systems.

Order entry systems enable nurses to order supplies and services from another department. Such systems eliminate the need for written order forms and expedite the delivery of needed supplies to a nursing unit. The **computerized physician order entry (CPOE)** is one type of order entry system gaining popularity in many larger hospitals. CPOE is a process by which the physician or nurse practitioner directly enters orders for patient care into the hospital information system. CPOE can eliminate the issues related to illegible handwriting and transcription errors, prevent duplication, and speed the implementation of ordered diagnostic tests and treatments. It can improve staff productivity and save money. Orders made through CPOE are integrated within the record and sent to the appropriate departments (e.g., pharmacy and radiology). In advanced systems, CPOE is linked to **clinical decision support**, which has a range of computerized tools such as built-in reminders and alerts that help the health care professional select the most appropriate medication or diagnostic test or remind the practitioner about drug interactions, allergies, and the need for subsequent orders. Medication errors and adverse drug-related events can potentially be reduced. Few studies have measured the effects of CPOE with clinical decision support on these variables, however, and more research (especially randomized controlled trials) in this area is needed (Wolfstadt et al., 2008).

The Electronic Health Record

The traditional paper health care record no longer meets the needs of today's health care industry. A paper record is episode oriented, with a separate record for each patient visit to a health care agency (Hebda et al., 2005). Key information can be lost from one episode of care to the next, which can jeopardize a patient's safety. An **electronic health record (EHR)** is a longitudinal record of patient health information accessible online from many separate but interoperable automated systems within an electronic network (Health Canada, 2005; see Chapter 16). A unique feature of an EHR is its ability to integrate all pertinent patient information into one record, regardless of the number of times a patient enters a health care system.

The development and implementation of an EHR to support effective health care delivery for Canadians is in progress through Canada Health Infoway, Inc. Infoway set a target of 50% of Canadians to have EHRs by 2010 and by December 2010, they had reached 49%. Canada is on schedule to providing EHRs to 100% of residents by 2016 (Canada Health Infoway, 2011).

Reporting

Nurses communicate information about patients so that all team members can make appropriate decisions about the care of patients. Any verbal report must be timely, accurate, and relevant. Many Canadian hospitals use the **situation-background-assessment-recommendation (SBAR) technique** or **identification-situation-background-assessment-recommendation-read back (I-SBAR-R) technique** (Box 15-8) to provide "a practical roadmap to succinct, important, but brief communication" between members of the health care team about a patient's care (Powell, 2007, p. 195). The SBAR/I-SBAR-R technique is a situational briefing system that fosters a culture of patient safety.

Nurses commonly make four types of reports: change-of-shift reports, telephone reports, transfer reports, and incident reports. The I-SBAR-R technique (see Box 15-8) can be incorporated into a variety of ways of reporting (e.g., a nurse's report to a physician about a critically ill patient, change-of-shift reports about individual patients) and can be adapted for use with or by other health care professionals.

Change-of-Shift Reports

At the end of each shift, nurses report information about their assigned patients to the nurses working on the next shift. There is an increasing awareness that high-quality handover practices are critical to ensure patient safety and continuity of care among nurses, but there is very little evidence for what constitutes best practice in change-of-shift reports (Riesenberg et al., 2010). Various terms are used to describe this exchange of information, such as change-of-shift reports, patient care handover, transfer of accountability, handoffs, bedside reporting, or shift handover.

Nurses give a **change-of-shift report** orally in person, by audiotape recording, by writing information on a summary report sheet, or during "walking-planning" rounds at each patient's bedside. Oral reports can be given in conference rooms, with staff members from both shifts participating. Oral reports can also take the form of one-to-one reports: for example, a report given by the night nurse to the day nurse. An advantage of oral reports is that they allow staff members to ask questions or clarify explanations. The nurses can see the patient together to perform needed assessments, evaluate progress, and discuss the interventions best suited to the patient's needs. An audiotape report is given by the nurse who has completed care for the patient; this type of report is left for the nurse on the next shift to review. However, it is essential to schedule an opportunity for the incoming nurses to ask questions for clarification after they listen to the taped report. According to Popovich (2011, p. 59), human factors such as "stress, distraction, and communication problems" make change-of-shift reports more prone to error. Several Canadian hospitals have implemented standardized bedside safe patient handoffs using **transfer of accountability (TOA)** practice guidelines developed by their institution. The process

► BOX 15-8

The Identification-Situation-Background-Assessment-Recommendation-Repeat Back (I-SBAR-R) Technique

When calling the physician, follow the I-SBAR-R process as follows:

Identification: Who is calling and who are you calling about?

- Identify yourself and your role
- Identify the unit, the patient, and the room number

Situation: What is the situation you are calling about?

- Briefly state the problem: What it is, when it started, and the severity

Background: Provide background information as necessary related to the situation, including the following:

- The admitting diagnosis, date of admission and pertinent medical history
- List of current medications, allergies, intravenous fluids, and laboratory tests
- Laboratory results (date and time each test was performed and results of previous tests for comparison)
- Other clinical information
- Code status

Assessment: What is your assessment of the situation?

Examples include the following:

- Most recent vital signs
- Changes in vital signs or assessment from previous assessments

Recommendations: What is your recommendation, or what do you think needs to be done?

Examples include the following:

- Patient to be admitted or transferred
- New medication or further tests
- Patient to be seen now
- Orders to be changed

Repeat Back:

- Repeat back orders that have been given
- Clarify any questions

Adapted from Joint Commission on Accreditation of Healthcare Organizations. (2005, February). The SBAR technique: Improves communication, enhances patient safety. *Joint Commission Perspectives on Patient Safety*, 5(2), 2; Enlow, M., Shanks, L., Guhde, J., & Perkins, M. (2010). Incorporating interprofessional communication skills (ISBARR) into an undergraduate nursing curriculum. *Nurse Educator*, 35(4), 176–180; and Grbach, W., Struth, D., & Vincent, I. (2007). *Reformulating SBAR to "I-SBAR-R"*. Chapel Hill, NC: Quality and Safety Education for Nurses. Retrieved from <http://www.qsen.org/teachingstrategy.php?id=33>.

provides an opportunity for “the off-going and the on-coming nurses [to] engage in a verbal report and [to] complete a patient safety checklist at the bedside” (Alvarado et al., 2006, p. 75).

Because nurses have many responsibilities, it is important to compile a change-of-shift report quickly and efficiently (Table 15-4). An effective report describes patients’ health status and tells staff on the next shift exactly what kind of care the patients require. A change-of-shift report should *not* simply be a reading of documented information. Instead, significant facts about patients are reviewed (e.g., condition of wounds, episodes of chest pain) to provide a baseline for comparison during the next shift. Data about patients need to be objective, current, and concise.

An organized report follows a logical sequence. The following is an example of a change-of-shift report:

► TABLE 15-4

Change-of-Shift Reports: Dos and Don'ts

Dos

Do provide only essential background information about patient (i.e., name, sex, age, physician's diagnosis, and medical history).

Do identify patient's nursing diagnoses or health care problems and their related causes.

Do describe objective measurements or observations about patient's condition and response to health problem, and emphasize recent changes.

Do share significant information about family members as it relates to patient's problems.

Do continuously review ongoing discharge plan (e.g., need for resources, patient's level of preparation to go home).

Do relay to staff significant changes in the way therapies are given (e.g., different position for pain relief, new medication).

Do describe instructions given in teaching plan and patient's response.

Do evaluate results of nursing or medical care measures (e.g., effect of back rub or analgesic administration), and describe results specifically.

Do be clear about priorities to which incoming staff must attend.

Don'ts

Don't review all routine care procedures or tasks (e.g., bathing, scheduled changes).

Don't review all biographical information already available in written form.

Don't use critical comments about patient's behaviour, such as “Mrs. Wills is so demanding.”

Don't make assumptions about relationships between family members.

Don't wait till near discharge to discuss the plan.

Don't describe basic steps of a procedure.

Don't explain detailed content unless staff members ask for clarification.

Don't simply describe results as “good” or “poor.”

Don't force incoming staff to guess what to do first.

Background information: Cy Tolan in bed 4, a 32-year-old patient of Dr. Lang, is scheduled for a colon resection this morning at 0800 hours. He has had ulcerative colitis for two years with recent bouts of frank bleeding in his stools. He was admitted at 0600 hours this morning with slight abdominal discomfort. This is his first experience with surgery. He knows he may require a colostomy. He has been NPO (had nothing by mouth) since midnight at home.

Assessment: Mr. Tolan mentioned that he was unable to sleep last night. He had many questions about surgery on admission this morning.

Nursing diagnosis: His chief nursing care problems are anxiety related to inexperience with surgery and risk for body image disturbance.

Teaching plan: I talked to him about postoperative routines and answered all his questions. He attended the preoperative admission clinic two weeks ago, but he did not have as many concerns at that time. He stated that he felt less anxious now that he knows what to expect.

Treatments: I started an intravenous infusion of normal saline in his left arm at 0645 hrs and it is running at 125 mL/hr.

Family information: His wife came with him this morning and will wait in the surgical waiting room till his surgery is complete.

Discharge plan: Mr. Tolan is a very active person and participates in strenuous sports such as swimming. Mrs. Tolan is concerned about how he might react to a colostomy. I suggest making a referral to the enterostomal therapist early, if the colostomy is performed.

Priority needs: Right now, Mr. Tolan is relaxing in his room. All preoperative procedures have been completed except for his preoperative antibiotic, due on call to the operating room.

A professional demeanour is essential when you give a report about patients or family members. It is often necessary to describe the interactions among patients, nurses, and family members in behavioural terms. Nurses must avoid using judgemental language such as *uncooperative*, *difficult*, or *bad* when describing such behaviours.

In many settings, unregulated care providers (UCPs) are involved in the change-of-shift report. UCPs are part of the health care team and can contribute more when they also know a patient's condition and the nursing team's priorities in care. The nurse can use the report to emphasize to UCPs the tasks that need to be accomplished.

Telephone Reports

Nurses inform physicians of changes in a patient's condition and communicate information to nurses on other units about patient transfer. The laboratory staff or a radiologist may phone to report results of diagnostic tests. Telephone reports should provide clear, accurate, and concise information. Information in a telephone report is documented when significant events or changes in a patient's condition have occurred. In documenting a phone call, the nurse includes information about when the call was made, who made it (if other than the writer of the information), who was called, to whom information was given, what information was given, and what information was received. An example is as follows: "At 1005 hrs called Dr. Morgan's office; S. Thomas, RN, was informed that Mr. Rush's stat potassium level drawn at 0800 hrs was 3.2. C. Skala, RN."

Telephone or Verbal Orders

A telephone order (often written "TO") involves a physician stating a prescribed therapy over the phone to a registered nurse. A verbal order (often written "VO") may be accepted when the physician has no opportunity to write the order, as in emergency situations. Clarifying for accuracy is important when you accept a physician's orders over the telephone or verbally. You need to verify the order by repeating it clearly and precisely. You are responsible for writing the order on the physician's order sheet in the patient's permanent record and signing it. An example is as follows: "1/16/2010, 1920 hrs: acetaminophen 325 mg PO [orally] 2 tabs now and q4h [every four hours] prn [as needed]. TO Dr. Reiss/Carol Skala, RN." The physician later verifies the telephone order legally by

BOX 15-9

Guidelines for Telephone Orders and Verbal Orders

- Clearly determine the patient's name, room number, and diagnosis.
- Repeat any orders back to the prescribing physician.
- Ask for clarification to avoid misunderstandings.
- Write telephone order ("TO") or verbal order ("VO"), including date and time, name of patient, and the complete order, and sign the names of the physician and nurse.
- Follow agency policies; some institutions require telephone (and verbal) orders to be reviewed and signed by two nurses.
- The physician must co-sign the order within the time frame required by the institution (usually 24 hours).

signing it within a set time period (e.g., 24 hours). Many telephone orders are given at night or during an emergency and need to be used only when absolutely necessary. In some situations, it may be prudent to have a second person listen to telephone orders. Box 15-9 provides guidelines that can be used to prevent errors when receiving telephone orders and verbal orders.

Transfer Reports

Patients may transfer from one unit to another to receive different levels of care. For example, patients transfer from an intensive care unit or the recovery room to general nursing units when they no longer require intense monitoring. To promote continuity of care, you may give **transfer reports** by phone or in person. When giving a transfer report, you need to include the following information:

- Patient's name, age, name of primary physician, and medical diagnosis
- Summary of progress up to the time of transfer
- Patient's current health status (physical and psychosocial)
- Patient's allergies
- Patient's emergency code status
- Patient's family support (e.g., spouse or partner, children, parents)
- Patient's current nursing diagnoses or problem and care plan
- Any critical assessments or interventions to be completed shortly after transfer (helps receiving nurse to establish priorities of care)
- Need for any special equipment, such as isolation equipment, suction equipment, or traction

After completion of the transfer report, the receiving nurse needs an opportunity to ask questions about the patient's status. In some cases, written documentation must include a record of information reported.

Incident Reports

An incident is any event that is not consistent with the routine operation of a health care unit or routine care of a patient. Examples of incidents include patient falls, needle-stick injuries, a visit by someone who has symptoms of illness, medication administration errors, accidental omission of ordered therapies, and circumstances that led to injury or risk for patient injury. Analysis of **incident reports** (also known as *adverse occurrence reports*) helps with the identification of trends in systems and unit operations that justify changes in policies and procedures or the scheduling of in-service seminars.

Incident reports are an important part of a unit's quality improvement program and should not be used for punitive purposes (see Chapter 10).

✦ KEY CONCEPTS

- The health care record is a legal document and requires information describing the care that is delivered to a patient.
- All information pertaining to a patient's health care management that is gathered by examination, observation, or conversation or as a result of treatment is confidential.
- Multidisciplinary communication is essential within the health care team.
- Accurate record keeping requires an objective interpretation of data with precise measurements, correct spelling, and proper use of abbreviations.
- A nurse's signature on an entry in a record designates that particular nurse's accountability for the contents of that entry.
- Any change in a patient's condition warrants immediate documentation to keep a record accurate.
- Problem-oriented health care records are organized by the patient's health care problems.
- The intent of SOAP, SOAPIE, PIE, and DAR charting is to organize entries in the progress notes according to the nursing process.
- Critical pathways or care maps provide members of the health care team with a way to document their contributions to the patient's total plan of care.
- Home care documentation is accessible to a variety of caregivers in the home.
- Long-term care documentation is multidisciplinary. Assessments performed several times a day in the acute care setting are required only weekly or monthly in long-term care.
- Computerized information systems contain information about patients that is organized and easily accessible.
- Protection of the confidentiality of patient health information and the security of computer systems should be a top priority.
- The major purpose of the change-of-shift report is to maintain continuity of care.
- When information pertinent to care is communicated by telephone or verbally, the information needs to be verified.
- Incident reports objectively describe any event that is not consistent with the routine care of a patient.

✦ CRITICAL THINKING EXERCISES

1. Joseph Vojnovic is an 80-year-old man admitted with a diagnosis of possible pneumonia. He complains of general malaise and a frequent productive cough, worse at night. Vital sign measurements are as follows: blood pressure, 150/90 mm Hg; pulse rate, 92 beats per minute; respiration rate, 22 breaths per minute; and temperature, 38.5°C. During your initial assessment, he coughs violently for 40 to 45 seconds without expectorating. He exhibits wheezes and coarse crackles at both bases of the lungs. He states, "It hurts in my chest when I cough." Differentiate between objective and subjective data in this case example.
2. The nurse positions Mr. Vojnovic in a semi-Fowler's position, encourages him to increase his fluid intake, and gives him acetaminophen (Tylenol), 650 mg PO, as ordered for fever. One hour later, his vital sign measurements are as follows: blood pressure, 130/86 mm Hg; pulse, 86 beats per minute; respiration rate, 22 breaths per minute; and temperature, 37.7°C. He states that he has been able to sleep. His fluid

intake over the past hour has been 200 mL of water. Use the given information to write a nurse's progress note using the PIE format.

3. Near the end of your shift, you have identified *fluid volume deficit* as a nursing diagnosis for Mr. Vojnovic. Since his admission, he has had a fluid intake of about 600 mL, and his urine output was 300 mL of dark, concentrated urine. His temperature is back up to 38.4°C, his mucous membranes are dry, and he states that he feels very weak. List what should be included in the change-of-shift report.
4. Several days later, after treatment with intravenous antibiotics, Mr. Vojnovic is feeling much better, and preparations are being made for discharge. He is to take cephalexin (Keflex) 500 mg every six hours, for the next 10 days; continue to drink extra fluids; and get extra rest. He lives alone. Although he is generally cooperative, he does not like drinking water or taking pills. He is to make an appointment with his physician for one week from today and should call the physician if symptoms recur. Write a discharge summary that is concise and instructive.

✦ REVIEW QUESTIONS

1. A fellow nursing student is a patient in the hospital where you have your clinical placement. You became aware of his admission when you transferred your own patient to his unit today. What should you do?
 1. Keep the information to yourself.
 2. Advise a few of his friends so that they can visit him.
 3. Visit him on his unit during your lunch break.
 4. Access his EHR to see if he is well enough for you to visit.
2. A manager is reviewing the nurses' notes in a community patient's health care record. She finds the following entry, "Patient is difficult to care for, refuses advice for improving appetite." Which of the following suggestions should the manager give to the community health nurse who entered the note?
 1. Avoid rushing when charting an entry.
 2. Use correction fluid to remove the entry.
 3. Draw a single line through the statement and initial it.
 4. Enter only objective and factual information about the patient.
3. A patient tells the nurse, "I have stomach cramps and feel nauseated." This is an example of which type of data?
 1. Objective
 2. Historical
 3. Subjective
 4. Assessment
4. During your visit to a patient's home, your patient says, "I do not know what is going on; I cannot get an explanation from my doctor about the results of my test. I want something done about this." Which of the following is the most appropriate documentation of the patient's emotional status?
 1. The patient has a defiant attitude and demands his test results.
 2. The patient appears to be upset with his physician about his test results.
 3. The patient is demanding and complains frequently.
 4. The patient states he is frustrated by the lack of information about his test results.

5. Patients frequently request copies of their health care records. Which of the following statements is true regarding patient access to health care records?
 1. Patients have the right to read those records.
 2. Patients are not allowed to read those records.
 3. Only the health care workers have access to the records.
 4. Only the families may read the records.
6. Accurate entries are an important characteristic of good documentation. Which of the following charting entries is most accurately written?
 1. Patient ambulated in hall with assistance, exercise well tolerated.
 2. Patient ambulated 15 m (50 feet) up and down hall, exercise well tolerated.
 3. Patient ambulated 15 m (50 feet) up and down hall with assistance from nurse.
 4. Patient ambulated 15 m (50 feet) with assistance from nurse. Pre-exercise HR 88; postexercise HR 94.
7. What is the purpose of acuity records?
 1. To guide all nursing care
 2. To document the patient admission
 3. To determine hours of care needed
 4. To establish guidelines for patient care
8. Match the correct numbered entry with the appropriate SOAP category.

S	1. Repositioned patient on right side. Encouraged patient to use patient-controlled analgesia.
O	2. "The pain increases every time I try to turn on my left side."
A	3. Acute pain related to tissue injury from surgical incision.
P	4. Left lower abdominal surgical incision, 3 inches (7.5 cm) in length, closed, sutures intact, no drainage. Pain noted on mild palpation.

❖ RECOMMENDED WEB SITES

Accreditation Canada: <http://www.accreditation.ca/en/>

Accreditation Canada is a national, nonprofit, independent organization whose role is to help health and social service organizations, across Canada and internationally, examine and improve the quality of care and service they provide to their patients through a voluntary external peer review.

Canada Health Infoway: <http://www.infoway-inforoute.ca>

Canada Health Infoway (Infoway) is a federally funded, independent, not-for-profit organization. Members include the 14 federal, provincial, and territorial deputy ministers of health. Infoway has a mandate to foster and accelerate the development and adoption of electronic health information systems and EHRs across Canada.

Canadian Nurses Association: Provincial and Territorial Regulatory Bodies: <http://www.cna-aic.ca/en/becoming-an-rn/regulation-of-rns/regulatory-bodies/>

This part of the Web site of the Canadian Nurses Association provides links to each provincial and territorial nursing association. Most associations provide information about documentation standards and requirements in their province or territory.

Canadian Nursing Informatics Association: <http://cnia.ca/>

The Canadian Nursing Informatics Association (CNIA) is affiliated with the Canadian Nurses Association and has been established as the voice for health informatics in Canada. *Nursing informatics* refers to the integration of nursing science, computer science, and information science to document and communicate data and knowledge in nursing practice.

Nursing Informatics and Canadian Nursing Practice

Written by Kathryn J. Hannah, RN, PhD, and Margaret Ann Kennedy, RN, PhD, CPHIMS-CA

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Differentiate how nursing informatics differs from routine use of technologies in nursing practice.
- Identify key Canadian issues and challenges in managing nursing data.
- Identify and compare Canadian strategies for identifying and documenting key nursing data.
- Discuss how health information data standards influence Canadian nursing practice.
- Discuss why using standardized nursing data is important for acknowledging the professional contributions of nursing to health outcomes of Canadians.
- Develop a beginning understanding of the scope of nursing informatics concepts and the ways in which nurses can be involved in nursing informatics.
- Discuss the relationship between national privacy legislation and nursing practice in a digital practice environment.
- Discuss how the Canadian Nurses Association's national *e-Nursing Strategy* will influence current and future nursing practice.

As health care systems respond to an increasingly complex technological environment, long-standing routines and tools are being superseded by strategic, evidence-informed practices that demand high-quality, timely health information. In an era when complex health care is delivered by dynamic multidisciplinary teams, effective nursing documentation is critical to support clinical judgment and decision making, as well as to support aggregation with documentation from other nurses and clinical disciplines to support optimal patient outcomes. Current information needs in health care

challenge nurses to identify the elements of their practice that are most critical for use in nursing decision making. **Nursing informatics (NI)**, a specialty area of nursing practice dedicated to optimal use of technology to support professional practice and enable optimal patient outcomes, has responded to this challenge and continues to support the progression of the effective use of information in nursing practice and documentation.

Hannah et al. (2006) tracked the evolution of technology in health care, noting that since its introduction in the health care sector, nursing has recognized the value of information and communications technology (ICT) to inform effective practice and has fostered technological development in support of patient care. Current ICT applications in health care include patient scheduling and transfer, billing and financial management, diagnostic imaging, lab reporting, order entry applications, pharmacy, patient documentation systems, clinical support tools, remote consultation and triage, as well as resource management applications. Developers of health care software solutions offer integrated suites of applications that incorporate multiple tools for health care facilities or regions, and many health care institutions customize software to meet specific needs. Efforts are underway in every Canadian province and territory to develop a jurisdictional **electronic health record (EHR)**—a longitudinal record of an individual's health status (including diagnosed morbid conditions), diagnostic tests, treatments, and results—that will be interoperable with a pan-Canadian EHR. This movement toward provincial and national EHRs requires that developers or vendors incorporate into their information systems the capacity for interoperability with other vendors' systems in order to provide the ability for patient information to be communicated along with the patients as they move across all sectors of the regional, provincial, or national health care delivery system.

However, in spite of the vast array of technologies currently available in health care, nurses must continue to contextualize technology within the scope of their professional practice. For example, Hannah (2005, p. 48) notes that “the issues for nurses are no longer computers or management information systems, but rather information and information management. The computer and its associated software are merely tools to support nurses as they practice their profession.”

Nursing Informatics and the Canadian Health Care System

As nurse leaders witnessed the technology explosion, pioneers in nursing informatics recognized that nursing needed to be strategic regarding the adoption of technology to support professional practice, and assess how nurses could respond to the demands related to using such technology. The term *nursing informatics (NI)* was introduced initially by Dr. Marion Ball at the 1983 International Medical Informatics Association (IMIA) Conference in Amsterdam (Hannah et al., 2006). In the 1980s, NI emerged as a new nursing specialty in health information management. Since the first text devoted to nursing informatics, by Ball and Hannah in 1984, journals and texts have proliferated across Canada and internationally. Hannah et al. (2006) noted that, despite the escalation of technology in health care and the recognition of NI, the persistent absence of universally accepted methods for defining and coding nursing contributions to health outcomes is a significant obstacle to the collection of nursing data.

Defining Nursing Informatics

As research, education, and practice continue to inform NI, and NI continues to advance, definitions have correspondingly evolved. Early definitions focused on technology and effective utilization in practice, while current definitions focus more on the role of information management and the role of the nurse as an information manager. Table 16-1 presents an overview summary of definitions, reflecting the progression in the understanding of NI and the concurrent evolution of definitions (Staggers & Bagley Thompson, 2002).

Evolution of Informatics in the Canadian Health Care System

The events occurring over the last 30 years have culminated in national attention to the need for timely, secure, and appropriate health information access. Multiple health care and standards development organizations operate to coordinate broad documentation of health information and monitoring of the Canadian health care system. It is essential that you have both an awareness and an understanding of the roles and relevance of each of these entities in relation to your nursing practice.

Health informatics encompasses all health care disciplines, and the unique application of informatics knowledge and skills reflects specialties such as medical informatics, nursing informatics, and dental informatics. The **Canadian Organization for Advancement of Computers in Health (COACH)**, Canada's health informatics association, defines health informatics as the “intersection of clinical, IM/IT [Information Management/Information Technology] and management practices to achieve better health” (COACH, 2009, p. 7). The recognition of health informatics occurred over many years as the result of dedicated efforts of many professionals. Although this chapter recognizes the existence of other types of informatics practices, the focus will remain on nursing informatics.

From the mid-1980s onward, Canada's health information infrastructure experienced numerous evolutions and reconfigurations, all of which had significant implications for nursing. The 1989 Canadian merger between the National Hospital Productivity Improvement Program and the Management Information System Project, which led to the Management Information System (MIS) Group, was an important event in Canadian health care information management (Hannah et al., 2006). The MIS Group, according to Hannah et al. (2006), developed guidelines on the collection of data for demographic, statistical, and resource utilization and consumption purposes. The problem with the MIS data is that, like hospital discharge summaries, this health information was restricted to physician-driven data and contained no clinical nursing data elements. Hannah et al. (2006, p. 89) made the point that “noteworthy, again, is the *total absence* of clinical nursing data.”

The Wilk Report (National Task Force on Health Information, 1991) had a significant effect on Canadian health information, triggering the 1993 merger of the Management Information System Group, Hospital Medical Records Institute, portions of Statistics Canada, and Health and Welfare Canada to create the **Canadian Institute for Health Information (CIHI)** (Hannah, 2005). CIHI is the national, independent, and not-for-profit body that records, analyzes, and disseminates essential data and analysis on Canada's health system and the health of Canadians (CIHI, 2011). Although not initially attentive to nursing data, this institution later became more important to

► **TABLE 16-1** Evolution of Nursing Informatics Definitions

Focus of Definition	Date	Author	Definition
Information technology	1984; 1994	Ball & Hannah (p. 181); Hannah et al. (p. 5)	"any use of information technologies by nurses in relation to the care of their patients, the administration of health care facilities, or the educational preparation of individuals to practise the discipline is considered nursing informatics"
	1986	Saba & McCormick (p. 116)	"systems that use computers to process nursing data into information to support all types of nursing activities"
	1989	Zeilstorff et al.	Central role of technology
	1996	Saba & McCormick (p. 226)	"use of technology and/or a computer system to collect, store, process, display, retrieve, and communicate timely data and information in and across health care facilities that administer nursing services and resources, manage the delivery of patient and nursing care, link research resources and findings to nursing practice, and apply educational resources to nursing education"
	1998	International Medical Informatics Association (IMIA; http://www.imia.org)	"the integration of nursing, its information, and information management with information processing and communication technology, to support the health of people worldwide"
	2000	Ball et al. (p. 10)	"all aspects of nursing—clinical practice, administration, research and education—just as computing holds the power to integrate all four aspects"
	2001	Canadian Nurses Association (http://www2.cna-aic.ca/CNA/documents/pdf/publications/NursingInformaticsSept_2001_e.pdf)	"the application of computer science and information science to nursing. NI promotes the generation, management and processing of relevant data in order to use information and develop knowledge that supports nursing in all practice domains"
Conceptual	1986	Schwirian (p. 134)	"solid foundation of nursing informatics knowledge [that] should have focus, direction, and cumulative properties"
	1989	Graves & Corcoran (p. 227)	A combination of computer science, information science, and nursing science designed to assist in the management and processing of nursing data, information, and knowledge to support the practice of nursing and the delivery of nursing care
	1996	Turley	Development of a NI model that included cognitive science, information science, and computer science
Role centred	1992	American Nurses Association (ANA) Council on Computer Applications in Nursing (p. 1)	"specialty that integrates nursing science, computer science, and information science in identifying, collecting, processing, and managing data and information to support nursing practice, administration, education, and research and to expand nursing knowledge. The purpose of nursing informatics is to analyze information requirements; design, implement and evaluate information systems and data structures that support nursing; and identify and apply computer technologies for nursing"
	1994	ANA (p. 1)	"specialty that integrates nursing science, computer science, and information science in identifying, collecting, processing, and managing data and information to support nursing practice, administration, education, research, and expansion of nursing knowledge. It supports the practice of all nursing specialties, in all sites and settings, whether at the basic or advanced level. The practice includes the development of applications, tools, processes, and structures that assist nurses with the management of data in taking care of patients or in supporting their practice of nursing"

▶ TABLE 16-1 Evolution of Nursing Informatics Definitions—cont'd

Focus of Definition	Date	Author	Definition
	2002	Staggers & Bagley-Thompson (p. 260)	Nursing informatics is a specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, and knowledge in nursing practice. Nursing informatics facilitates the integration of data, information, and knowledge to support patients, nurses, and other providers in their decision making in all roles and settings. This support is accomplished through the use of information structures, information processes, and information technology.
	2009	International Medical Informatics Association—Nursing Informatics (IMIA-NI)	Nursing informatics science and practice integrates nursing, its information and knowledge and their management with information and communication technologies to promote the health of people, families, and communities globally.

several issues directly influencing nursing, including issues related to nursing workforce recruitment and retention.

In response to recommendations issued by the National Forum on Health for a pan-Canadian electronic health record, the federal government committed an initial \$500 million to the development of e-health, which included the EHR, telehealth, and Internet-based health information (Canadian Nurses Association [CNA], 2006b; Hannah, 2005). **Canada Health Infoway** (Infoway), incorporated in 2001, was a key outcome of the federal, provincial, and territorial partnership (CNA, 2006a). Infoway has a national mandate to generate consensus on health information standards, to drive the national agenda of creating an EHR system, and to act as the liaison to international standards development organizations (Canada Health Infoway, 2012). Infoway fulfills this mandate by partnering with jurisdictions as a “strategic investor” to share costs of implementing health information management projects and provides additional project benefits analysis. Since 2001, the federal government has allocated \$2.1 billion to Infoway to support the development of electronic health records in Canada (Canada Health Infoway, 2012).

Six core components make up an EHR (Canada Health Infoway, 2012):

- Patient registry
- Provider registry
- Diagnostic images
- Laboratory results
- Drugs dispensed
- Clinical reports/immunization

To date, nine jurisdictions in Canada have at least four of these components in place, while the other jurisdictions are in various stages of implementation (Canada Health Infoway, 2012). Additional information about the EHR is available at <https://www.infoway-inforoute.ca/>.

Since its inception, Infoway has approved allocation of more than \$2 billion, or 96.8% of its total funding, across all its program areas (Canada Health Infoway, 2012, p. 22). To date, Infoway has committed more than \$953.5 million to various provincial and territorial projects and programs, resulting in more than 371 projects in various stages of evolution ranging from planning to near completion (Canada Health Infoway,

2012). See Figure 16-1 for the status of jurisdictional progress on establishing the components of EHRs.

Projects vary in nature—telehealth, registries, picture archiving and communication systems (PACS), and lab and drug information systems—all enabling a faster response time between assessment and treatment. Every province and territory in Canada is engaged in advancing the implementation of EHRs, and, with investment from Infoway, they are making progress toward providing this service to Canadians.

Standards in Health Informatics

Standards in health care data management refer to a nationally or internationally agreed-upon protocol for representing all types of health information, including types of care provided, location of care provision, pharmacy ordering and dispensing, and billing messages. Standards ensure that data are consistently represented and exchanged and thus consistently *understood* by practitioners and health information systems. This consistent understanding and interpretation of health data contribute to the provision of quality care as well as increasing patient safety.

Infoway (2012) notes that standards ensure interoperability by supporting information exchange and identifies standards as a critical foundation for the interoperable electronic health record (iEHR). Canada Health Infoway (2012, p. 5) demonstrates how “standards support integrated, patient-centric health records enabling a longitudinal view of an individual’s key health history and care ... and that this critical information can be updated, managed, shared and interpreted in a meaningful secure way, when and where required.” Additional benefits of standards to various stakeholder groups are identified in Box 16-1.

In 2006, Infoway launched the Standards Collaborative, which is a “Canada-wide coordination function created to support and sustain health information standards in Canada” (Canada Health Infoway, 2008, p. 4). The global mandate for the Standards Collaborative was endorsed by the federal, provincial, and territorial Ministries of Health to coordinate support for development, implementation, testing, and maintenance of standards, and education for

► BOX 16-1 Benefits of Standards for Stakeholder Groups

Stakeholder Group	Benefits of Standards in Health Care Data
Patients	• Reduced repetition of health information • Accessible personal health history • Improved coordination of care • Reduced duplication of tests and procedures • Improved health outcomes
Providers	• Timely access to health data • Availability of more reliable health information • Reduced duplication of efforts • Shorter response time between assessment and treatment • Improved quality and consistency of care resulting from enhanced information access • Enhanced patient outcomes
Service delivery organizations	• Reuse of solutions, benefiting from lessons learned and change management strategies • Greater breadth of data to use for evaluating outcomes • Enhanced ability to work collaboratively with other organizations or jurisdictions
Educators	• Increased confidence in products when determining suitability for use • Support for curriculum design that is aligned with accreditation process • Increased value of data for educational purposes • Enabling of educators and students to understand the health informatics environment at early stages of education
Researchers	• Enhanced ability to extract data, such as best practice guidelines, from published sources • Availability of higher-quality data • Reduced time to prepare data for use • Comprehensive data sets • Improved ability to monitor and assess health outcomes and determinants

both general and specific user groups (Canada Health Infoway, 2010, 2008).

The Standards Collaborative also incorporates nine Standards Collaborative Working Groups (SCWGs), in which clinicians, information technology experts, academics, researchers,

and policymakers collaborate to address standards development for health information and information systems in Canada. Membership in these groups is voluntary and open to any individual with an interest in contributing to the development of a specific aspect of EHRs.

Nurses are critical contributors to standards both in Canada and internationally. As a beginning practitioner, you need to be aware of the reasons you should participate; think of what the value is to you professionally and to the nursing profession to have nurses actively contributing and your role in contributing to the development and adoption of meaningful standards.

Standards Development in Canada

Canada is unique in providing a centralized access point for the development, use, and maintenance of health information standards. The Standards Collaborative provides support for domestic health information standards, international standards that are adopted for Canadian use, related services and customized education opportunities, maintenance and terminology services, implementation support, and the international Standards Development Organization (SDO) liaison on behalf of Canada.

The Standards Collaborative establishes pan-Canadian standards to support interoperability and promotes pan-Canadian consensus by leveraging and harmonizing the efforts of the federal, provincial, and territorial jurisdictions, health care providers, vendors, academics, and a comprehensive range of Canadian agencies and associations (Canada Health Infoway, 2012). As of 2011, standards supporting all six key components of the Electronic Health Record Solution (EHRS) and the EHRS Blueprint have been developed in Canada (Canada Health Infoway, 2012, p. 5). In addition to the standards established by the Standards Collaborative, access to international standards is also facilitated.

There are a number of ways in which **standards** play a role in shaping health care data. Standards support both *technical needs* regarding consistent communication of health data and *business needs* regarding actual clinical work processes—for example, a gap may be identified where we need to consistently describe a particular condition or clinical situation. Clinical terminology standards such as **SNOMED CT**® (Systematized Nomenclature of MEDicine Clinical Terms®) and others influence how we document clinical practice and access health data.

Standardizing Nursing Language

A widely held perception among many nurses is that nursing, as a professional practice, is generally considered invisible in regards to formal and tangible recognition (Clark, 1999; Clark & Lang, 1992; CNA, 2000; Hannah et al., 2006; Marck, 1994; Norwood, 2001; Powers, 2001; Weyrauch, 2002). Clark (1999, p. 42) observed that, in spite of representing the largest group of health care clinicians, nursing was invisible in health policy decisions, in descriptions of health care, in contracts, and in service specifications.

Clark and Lang (1992, p. 109), in their assessment of the invisibility of nursing, noted that nurses cannot control what cannot be named, stating “If we cannot name it, we cannot control it, finance it, teach it, research it, or put it into public policy.” The stance put forward by Clark and Lang (1992) and other seminal works (such as Graves & Corcoran, 1989, and Werley, 1988) argues that in order to give nursing visibility, it requires a standardized language to reflect what nursing is and what nursing does. Clark (1999) advocated a standardized nursing language, using the argument that “without a language to express our concepts we cannot know whether our understanding of their meaning is the same, so we cannot

communicate them with any precision to other people” (Clark 1999, p. 42). More recently, the argument has shifted from the issue of visibility to the value and necessity for patient safety and accountability along with accurate data for health system and clinical evaluation. Adopting a standardized nursing language has never been a more urgent issue, as the pan-Canadian iEHR moves forward and information management further enables evidence-based practice.

Health Information: Nursing Components

Before a standard nursing language is adopted, it is necessary to identify the most important data elements required for effective nursing decision making and evaluation. The minimum number of essential nursing data elements are referred to as a *minimum nursing data set*. In Canada, the process of working toward capturing nursing data was led by the Alberta Association of Registered Nurses (AARN) in 1992. This provincial nursing body, in conjunction with the Canadian Nurses Association, hosted a national conference focused on generating and validating a Canadian nursing minimum data set (NMDS) (Giovannetti et al., 1999). The nursing components of health information, the Canadian version of an NMDS, is known as **Health Information: Nursing Components (HI:NC)**. Since 1992, there has been consensus among Canadian nurses that HI:NC comprises five categories of elements: patient status, nursing interventions, patient outcomes, nursing resource intensity, and primary nurse identifier (AARN, 1994; CNA, 2000, 2001b). The Canadian Nurses Association describes HI:NC as the “most important pieces of data about the nursing care provided to the client during a health care episode” (2000, p. 5). Table 16-2 presents the HI:NC definitions.

Chapter 15 provides an overview of computerized nursing documentation. Many clinical information systems incorporate the HI:NC into the architecture or design of the nursing system. This enables capture of the most significant data reflective of the nursing contribution to patient care. Many versions of computerized nursing documentation systems continue to evolve and rely on the underlying philosophy of documentation to support design. For example, many systems do not encourage narrative documentation but provide checklists of common activities and encourage exception charting. Please review Chapter 15 for additional discussion of this issue.

International Classification for Nursing Practice®

In 2001, CNA endorsed the **International Classification for Nursing Practice® (ICNP®)** “for use in Canada as a foundational classification system for nursing practice in Canada” (CNA, 2001a). This endorsement was renewed in 2006 (CNA, 2006b). ICNP® was developed by the **International Council of Nurses (ICN)** in response to concerns regarding the visibility of nursing contributions in health care and calls for standardization of nursing data for comparability and analysis, as well as evidence-based practice. ICN proposed the use of a single unified terminology to represent nursing practice. The goals were to capture nursing practice across practice settings, cultures or languages, and geographical settings, as well as to ensure that professionals who used this new terminology could communicate with the numerous nursing terminologies already in use. Initially endorsed for development in 1989 by resolution at the ICN 19th Quadrennial Conference (ICN, 2009), the Alpha version of the International Classification for Nursing Practice® (ICNP®) was released in 1995. Version 1.0 was released in 2005 and is substantively different from

► TABLE 16-2

Health Information: Nursing Components

Nursing Component

Definition

Patient status	A label for the set of indicators that reflect the phenomena for which nurses provide care, relative to the health status of patients (McGee, 1993). Although patient status is similar to nursing diagnosis, the term <i>patient status</i> is preferred because it represents a broader spectrum of health and illness. The common label <i>patient status</i> is inclusive of input from all disciplines. The summative statements referring to the phenomena for which nurses provide care (i.e., nursing diagnosis) are merely one aspect of patient status at a point in time, in the same way as medical diagnosis.
Nursing interventions	Purposeful and deliberate health-affecting interventions (direct and indirect), based on assessment of patient status, which are designed to bring about results that benefit patients (Alberta Association of Registered Nurses [AARN], 1994).
Patient outcome	The "clients' status at a defined point(s) following health care [affecting] intervention" (Marek & Lang, 1993). It is influenced to varying degrees by the interventions of all care providers.
Nursing intensity	"Refers to the amount and type of nursing resource used to [provide] care" (O'Brien-Pallas & Giovannetti, 1993)
Primary Nurse Identifier	A single, unique, lifetime identification number for each individual nurse. This identifier is independent of geographic location (province or territory), practice sector (e.g., acute care, community care, public health) or employer.

subsets of diagnoses, actions, and outcomes specific to various practice areas or specialties (such as wound care) and continue to be developed. To begin catalogue development, nurses select a health care topic based on the needs of patients. The organization of the catalogue content would be determined by the nurses as ICNP® diagnoses, outcomes, and interventions are identified. ICN (2010) suggested that catalogues can fill a practical need in building health information systems with all the benefits of being part of a unified nursing language.

As stated earlier, the Canadian Nurses Association endorsed ICNP® as the terminology for documenting professional nursing practice in Canada (CNA, 2001a, 2006b). Although Canada Health Infoway, in consultation with various stakeholder groups, adopted SNOMED CT® as the terminology for the pan-Canadian electronic health record, ICNP® remains the preferred terminology for nursing. ICN, which holds the intellectual property rights to ICNP®, is in discussion with the **International Health Terminology Standards Development Organization (IHTSDO)**, which holds the intellectual property rights for SNOMED CT®, to identify means of linking between the two standardized clinical terminologies to ensure that nursing practice is accurately documented. Initial efforts on this linking are using the ICNP C-HOBIC catalogue (ICN, 2011) to test the methodology for linking ICNP® and SNOMED CT. Validation results were anticipated by July 2012. Innovative tools such as C-Space (see Figure 16-3) are being used in the validation process to leverage the expertise and contributions of the international community.

As illustrated in Figure 16-2, ICNP® Version 2.0 is constructed using seven axes: Focus, Judgement, Means, Action, Time, Location, and Patient. Table 16-3 lists definitions for each axis and examples of terms. According to ICNP® requirements,

previous iterations (Alpha, Beta, Beta 2), using a single 7-Axis Model to unify all previous ICNP® axes (see Figure 16-2). The ICNP® is a unified nursing language system. It is a compositional terminology for nursing practice that facilitates the development of and cross-mapping among local terms and existing terminologies (ICN, 2009). ICNP® Version 2 was launched on July 2, 2009, at the ICN 24th Quadrennial Congress in Durban, South Africa, and moved ICNP® forward with the addition of new content, including many new pre-coordinated nursing diagnosis, intervention, and outcome statements as well as the inclusion of catalogues (ICN, 2010).

ICNP® is used to generate statements of nursing diagnoses, nursing actions, and nursing outcomes, using terms arranged in a hierarchical order and in catalogues (or subsets) of pre-combined terms. Catalogues are made up of nursing data

Figure 16-3 Structure of International Classification for Nursing Practice® (ICNP®), Version 2.0, 2011 Release. **Source:** ICN C-Space. Reproduced with permission of the International Council of Nurses © 2012.

► **TABLE 16-3**

Definitions and Examples of Terms in ICNP® Version 1

Axis	Definition	Sample Terms
Focus	The area of attention relevant to nursing	<i>Elder abuse, sputum, air, child labour law</i>
Judgement	Clinical opinion or determination related to the focus of nursing practice	<i>High, enhanced, partial, risk</i>
Means	A manner or method of accomplishing an intervention	<i>Wound drainage bag, nebulizer, bed rail, cardiac monitor</i>
Action	An intentional process applied to or performed by a patient	<i>Violence prevention, explaining, listening, resuscitating</i>
Time	The point, period, interval, or duration of an occurrence	<i>Rarely, chronic, discharge, intermittent</i>
Location	Anatomical or spatial orientation of a diagnosis or intervention	<i>Chest wall, distal, residential building, supine, intravenous route</i>
Patient	Subject to which a diagnosis refers and who is the recipient of an intervention	<i>Extended family, community, adolescent, elder, infant</i>

Adapted from International Council of Nurses. (2009). *International Classification for Nursing Practice®*, Version 2.0 (p. 12). Geneva, Switzerland: Author. Reproduced with permission of the International Council of Nurses, copyright © 2005.

both nursing diagnoses and nursing outcomes *must* contain a term from the Focus axis and the Judgement axis and may include terms from additional axes as needed to fully describe the phenomenon of attention. Nursing Interventions *must* include a term from the Action axis and the Target axis and may include additional terms from other axes as necessary. ICN (2009) describes a “Target term” as a term originating in any axis except the Judgement axis.

You should keep in mind that the format of these nursing diagnosis statements may not correspond with those identified in previous chapters. The examples below reflect the core details for coding key nursing data in the EHR. These may not (and possibly will not) be used in daily communication among nurses, but rather for aggregation purposes in the EHR. Some examples of nursing statements using ICNP® Version 2.0 include the following:

Nursing Diagnosis: *Decreasing level of pain in right knee joint.*

Pain is from the Focus axis,

Decreasing level is from the Judgement axis

Both *right* and *knee joint* are from the Location axis

Nursing Intervention: *Analgesia injected*

Injected and *injecting* are from the Action axis

Analgesic is from the Means axis

Nursing Outcome: *Sputum decreased*

Sputum is from the Focus axis

Decreased is from the Judgement axis

As with all languages, development of ICNP® is continuous, with research underway in many countries (Boxes 16-2 and 16-3). Version 2.0 is subjected to ongoing evaluation to refine and enhance terms, catalogues, and translations.

Canadian Privacy Legislation

Although both provincial standards of practice and the CNA (2008a) *Code of Ethics* address confidentiality, you also need to be aware of Canadian privacy legislation affecting nursing practice and the protection of patient data. Even as you fulfill the standards of practice, it is possible to violate privacy

* BOX 16-2 RESEARCH HIGHLIGHT

Evaluating Standardized Nursing Terminology

Research Focus

Nursing data have not been included in national data repositories for a variety of reasons, including the lack of a single nursing terminology to describe the nursing contribution to patient/client care (i.e., nursing practice). Consequently, health care decisions have been made in the absence of valuable nursing data. The need for a standardized nursing language stimulated the development of the ICNP®. Testing was necessary to evaluate the representational capacity of this terminology for Canadian nursing practice. Kennedy (2005) examined the effectiveness of the ICNP® in representing the contributions of nursing to health care outcomes in Canada. The ICNP® was used to code retrospective nursing data extracted from patient records originating in acute care, in-patient mental health, home health care, and long-term care practice settings. In spite of a wide variation in documentation practices, ICNP® achieved matches with a significant majority of nursing data, thereby confirming the utility of ICNP® for documenting nursing practice in Canada.

Representing Nursing Practice

ICNP® represents Canadian nursing practice with high accuracy. Variations and gaps in nursing documentation practices are further evidence of the need for standardized terminology to ensure that at least minimum nursing data are recorded.

> BOX 16-3 Creating Canadian Nursing History

The C-HOBIC Initiative

The CNA launched a multiprovince project in 2007, with financial investment by Canada Health Infoway, focused on collecting information reflecting evidence-based, nursing-sensitive patient outcomes (CNA, 2008b). Drawing on the work of the original **HOBIC (Health Outcomes for Better Information and Care) Project**, the **C-HOBIC (Canadian Health Outcomes for Better Information and Care) Project** (http://www2.cna-aic.ca/c-hobic/toolkit/default_e.aspx) is implementing a standardized nursing documentation approach for capturing, analyzing, and reporting nursing-sensitive outcomes for acute care, complex continuing care, long-term care, and home care.

The C-HOBIC project addresses gaps in health information related to nursing's contribution to patient outcomes and also addresses the need for standardized nursing data for inclusion on patient admission and discharge summaries. The major components of this project are a systematic approach to gathering nursing content that is documented using a standardized clinical terminology and coded in a format suitable for inclusion in the electronic health records being developed or implemented by the participating provinces. This project requires use of a standardized clinical terminology, International Classification for Nursing Practice® (ICNP®), and provides an opportunity for Canadian nurses to make substantive contributions to the ongoing development of ICNP®. One particular aspect of the C-HOBIC project was the mapping of outcomes concepts to the ICNP® Version 1.0.

Mapping challenges provided an immediate opportunity for Canadian nurses to contribute to the iterative development of ICNP® by proposing multiple new terms and to a catalogue of precombined terms for inclusion in ICNP® that are uniquely Canadian and reflect C-HOBIC concepts. The mapping was validated at a national forum (Kennedy, 2008; Kennedy et al., 2008) that included C-HOBIC partners, nursing informatics experts, nurse educators, nurse researchers, representatives from government ministries, policy institutions and practice environments, and two international ICNP® experts.

In total, 96 concepts were addressed in the mapping aspect of the C-HOBIC project: 58 HOBIC concepts were matched and validated as C-HOBIC terms, 13 HOBIC concepts were partially mapped to ICNP®, and a new term was required in ICNP® in order to fully communicate the original concept in C-HOBIC; 24 concepts did not match, and new C-HOBIC terms were proposed for inclusion in ICNP®, and only one HOBIC concept ("Activity did not occur") could not be mapped to ICNP®. In addition, two HOBIC ordinal scales were retained for use in C-HOBIC, including the pain scale and the number of falls. Consensus by the group was achieved for all concepts, terms, and issues. Critical next steps include the creation of the C-HOBIC catalogue by ICNP® and the establishment of a nursing terminology working group.

On January 11, 2012, the Standards Collaborative Strategy Committee (the most senior committee) endorsed the C-HOBIC/ICNP Data Set as a Canadian Approved Standard (CAS). This is the first nursing data standard approved as CAS, and Canada is the first country in the world to approve an ICNP® Catalogue as a national standard.

legislation. Canadians recognize this risk of privacy violation, and "two thirds of Canadian citizens believe that personal health information is one of the most important areas in need of protection under privacy laws" (Roch, 2008, p. 8). Although privacy legislation varies among provinces, you must develop a working knowledge of the relevant legislation supporting health information protection (Gershon & Tu, 2008), both provincial and national.

Two federal legislative acts address the protection of personal information. These are the *Privacy Act* and the *Personal Information Protection and Electronic Documents Act (PIPEDA)* (Government of Canada, 2004). Both acts identify specific limitations to the disclosure of personal information—whether in electronic or other forms. Regardless of the practice setting or mode, you are professionally, ethically, and legally obligated to protect all personal information of patients in your care (Box 16-4). Knowledge of these two pieces of federal privacy legislation can help you uphold the standards of practice and *Code of Ethics*.

According to the *Privacy Act*, Section 8.1, "Personal information under the control of a government institution shall not, without the consent of the individual to whom it relates, be disclosed by the institution" (Government of Canada, 1983). The PIPEDA is federal legislation governing the disclosure of personal health information in any electronic environment. This act extends the *Privacy Act* by addressing specific risks associated with electronic data collection, storage, retrieval,

and communication. The purpose of the PIPEDA, as updated in March 2006, is to "establish, in an era in which technology increasingly facilitates the circulation and exchange of information, rules to govern the collection, use and disclosure of personal information in a manner that recognizes the right of privacy of individuals with respect to their personal information and the need of organizations to collect, use, or disclose

► BOX 16-4

Distinguishing Types of Protected Information

PIPEDA distinguishes “personal information” from “personal health information” and provides specific definitions for both:

“Personal health information,” with respect to an individual, whether living or deceased, means

- (a) information concerning the physical or mental health of the individual;
- (b) information concerning any health service provided to the individual;
- (c) information concerning the donation by the individual of any body part or any bodily substance of the individual or information derived from the testing or examination of a body part or bodily substance of the individual;
- (d) information that is collected in the course of providing health services to the individual; or
- (e) information that is collected incidentally to the provision of health services to the individual.

“Personal information” means information about an identifiable individual but does not include the name, title, or business address or telephone number of an employee of an organization.

Source: Personal Information Protection and Electronic Documents Act, S.C. 2000, c. 5. Retrieved from <http://laws-lois.justice.gc.ca/eng/acts/P-8.6/page-1.html#h-3>.

personal information for purposes that a reasonable person would consider appropriate in the circumstances” (Department of Justice, 2011, <http://laws-lois.justice.gc.ca/eng/acts/P-8.6/page-2.html#h-5>). Furthermore, PIPEDA restricts the disclosure of personal information to only the most stringent of conditions, such as law enforcement requirements (Government of Canada, 2004, Division 1, Section 7.3).

PIPEDA was initially applicable only to personal information collected or used in commercial activities by private-sector entities regulated by the federal government. However, the act has been extended over time to cover the retail sector, publishing companies, the service industry, manufacturers and other provincially regulated organizations, and sector-specific data such as health information.

PIPEDA applies to Canadian jurisdictions unless the federal government acknowledges an exemption based on provincial legislation that is substantially similar. As of 2011, only British Columbia, Alberta, Quebec, and most recently Ontario are considered to have legislation substantially similar to PIPEDA (Office of the Privacy Commissioner, 2011). Despite provincial acts taking precedence within provinces, federal legislation continues to govern the transmission of personal information across and between provincial boundaries.

In addition to domestic legislation, other factors also affect the privacy of the EHR. Infoway’s privacy mandate is to support private, secure, and protected information in the EHR. In the course of doing so, Infoway, the Standards Collaborative, and their partners leverage applicable international standards (for example, from the International Organization for Standardization) that operate in alignment with Canadian legislation and further support the privacy and security of health data in electronic health care systems. You can review the scope of privacy activities for initiatives in which Infoway invests and for Standards Collaborative activities at the following Web page: <https://www.infoway-inforoute.ca/privacy-mandate>.

Despite the complex nature of privacy legislation and the standards that support privacy activities, you must exercise diligence in examining and applying these pieces of legislation to your professional nursing practice. You can review the privacy legislation in your province by going to this link: http://www.priv.gc.ca/resource/prov/index_e.cfm. Please refer to Chapter 15 to explore how PIPEDA relates to specific nursing documentation.

National e-Nursing Strategy

The CNA (2006a) released the *e-Nursing Strategy for Canada* to direct the coordinated integration of technology into Canadian nursing practice. The strategy addresses both medium- and long-term targets, with the overall goal of improving both nursing practice and outcomes for patients and clients. This strategy is intended to completely integrate ICT in such a way that the “e” in *e-nursing* is no longer required. ICT will simply be another tool that nurses use in their practice (CNA, 2006a). The CNA (2006a, p. 4) identified seven key outcomes that are projected to emerge from the *e-Nursing Strategy*:

1. Nurses will integrate ICT into their practice to achieve desirable patient outcomes.
2. Nurses will have the required information and knowledge to support their practice.
3. Human resources planning will be facilitated.
4. New models of nursing practice and health services delivery will be supported.
5. Nursing groups will be well connected.
6. ICT will improve the quality of nurses’ work environments.
7. Canadian nurses will contribute to the global community of nursing.

Three fundamental directions for the CNA’s *e-Nursing Strategy* were developed among working groups and national feedback: access, competencies, and participation. Access to quality ICT in the practice environment is imperative if Canadian nurses are to realize the full benefits of technology in their practices. The CNA (2008b) noted that health care organizations have a responsibility to ensure that nurses have connectivity—tools such as computers, mobile technology (e.g., laptops, smart phones and mobile tablets, wireless technology), as well as resource databases and Internet resources—that will support professional practice.

The CNA (2008b) encourages nurses to develop *competencies* in the application of ICT and recommended that such competencies be part of both undergraduate and graduate-level nursing programs. Just as you have a responsibility to develop competencies in performing a variety of patient care tasks, such as assessments and treatments, it is also your responsibility to develop and maintain competencies in technological applications that support information management in professional practice. Informatics and information management competencies are now included in the *Canadian Registered Nurse Examination* and are integrated throughout the Canadian Registered Nurse Examination Competencies for June 2010–May 2015 (CNA, 2010). To that end, an initiative (Canada Health Infoway, 2011), by the Canadian Association of Schools of Nursing (CASN) and Canada Health Infoway (Infoway) is intended to prepare nursing students for practice in modern, technology-enabled clinical environments. Through this initiative, CASN, with investment by Infoway, is working toward providing faculty and nursing students with the

BOX 16-5

CASE STUDY: ROLE OF AN ELECTRONIC COMMUNITY OF PRACTICE (eCOP) TO CREATE INTEREST AND POSITIVE ATTITUDE TOWARD NURSING INFORMATICS: THE BC EXPERIENCE

By Elizabeth Borycki and Noreen Frisch, University of Victoria Schools of Health Information Science and Nursing; Co-Leaders of the InspireNet eHealth Action Team

Nurses in British Columbia are connecting! For the purpose of garnering interest in nursing health services research, the BC Nursing Research Initiative through the Michael Smith Foundation for Health Research has funded a BC Nursing Health Services Research Network, now renamed as InspireNet (Innovative Nursing Services and Practice Informed by Research and Evaluation). Among InspireNet's goals are to create collaborative advantages by bringing like-minded people together to foster research, knowledge translation, and practice readiness. Based on an understanding that connections between and among people who are geographically dispersed requires virtual connections, InspireNet uses Web 2.0 and 3.0 technologies to conduct its work "virtually" through a Web site and by organizing its members into action teams that function as communities of practice. Wenger and others describe communities of practice as groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in the area of that topic by interacting on an ongoing basis. Electronic communities of practice (eCOPs) use social networking capabilities to support the establishment and work of groups of people.

After 18 months in operation, the InspireNet project had over 800 members connecting to each other through an e-newsletter, a password-protected database of members, a monthly blog prepared by members on current topics, and password-protected memberships in eCOPs called "InspireNet Action Teams." The Action Team eCOPs are formed around topics or areas of interest. Perhaps not surprisingly,

nurses interested in all of the various aspects of informatics were early adopters of an eCOP, which they have labelled the eHealth, eTechnologies and Informatics Action Team.

In an area of nursing where nurses are covering new ground (like informatics), and where nurses who have an interest in the topic may be few and far between, the connections found in a virtual environment can be critical. The InspireNet eHealth eCOP has brought over 50 nurses together in a short period of time. They have tuned into Web-based conferencing to learn about and discuss issues such as basic informatics, the need for education to address informatics, and the state of informatics work in their province. They have connected nurses who work in information technology units with nurses who work in professional practice offices. They have learned about membership in Canadian Nursing Informatics Association (CNIA) and have had speakers from afar (from Canada) on topics such as C-HOBIC and (from Europe) on demonstrations of fully implemented electronic nursing documentation systems. They have established a journal club to learn about some of the latest work in nursing informatics. And they have accomplished all of these activities without leaving home!

We encourage you, as beginning students in nursing, to participate in exploring the role that networking can play in your professional development and support. For starters, we recommend exploring membership in nursing organizations (such as the CNIA) for the purpose of finding those with similar interests as yours and seeking to establish connections with other nurses who wish to make a difference in Canadian nursing practice.

Networking may well be the future of social capital for nurses. Try it out for yourself!

Reference: Wenger, E., McDermott, R., & Snyder, W. (2002). *Cultivating communities of practice*. Boston: Harvard Business School Press. For further information, go to <http://www.InspireNet.ca>.

knowledge, tools, and support they need to teach, learn, and practise in technology-enabled practice settings. Educators, informatics experts, and students at the 91 nursing degree-granting colleges and universities across Canada are participating in a three-year effort to strengthen learning about effective uses of ICT, now essential tools in clinical practice. Key program components focus on the development, evaluation, and sharing of curriculum-based resources and e-learning tools.

Many examples of innovative nursing practice incorporating information and communications technology are evident in Canada (Box 16-5). Two such examples are the mobile wound assessment program used by the Victorian Order of Nurses and the standardized assessment approaches currently being integrated in the Local Health Integration Network (LHIN) in Ontario. Goodwin et al. (2008) combined telemedicine and telemonitoring with patient education and peer supports in assisting chronically ill patients to stay at home in rural Ontario. Without this program, these patients would have had to travel for care provision and would have potentially experienced more frequent hospitalizations, loss of independence, and significantly less self-care. Tracey (2008) described how a standardized assessment approach is in pilot testing at two sites. This pilot format will ultimately replace six different assessment forms, contributing to more

systematic data collection and greater capacity for data aggregation and analysis.

The CNA (2006a, p. 12) identified *participation* as including strategic partnerships with nurses in clinical practice; with employers and administrators; with federal, provincial, and territorial ministries; with nursing organizations (professional associations, regulatory bodies, educational groups, and unions); and with educators and researchers. The concept of partnership has far-reaching consequences: with effective partnerships, you can contribute to the selection and design of information technology applications, as well as contributing to educational programs. For example, many health care institutions and agencies have clinical committees that collaborate with IT experts in the design and selection of electronic documentation systems. Especially as a novice nurse, you have both the knowledge and opportunity to contribute your insights about which information management systems are user friendly or present unexpected challenges. It is also helpful to have this type of clinician involvement when system revision or adaptation is required. Even small changes can sometimes have a significant impact on the capture of appropriate nursing data and how nurses view the system. Without partnerships, however, you, and all nurses, risk being excluded from decision making and using systems that are selected without valuable clinician contributions.

The Canadian Nurses Association portal, NurseONE, is a key component of the *e-Nursing Strategy*. The portal was initially funded from a grant from the First Nations and Inuit Health Branch (FNIHB) of Health Canada (CNA, 2006c). The nursing portal, now known as NurseONE, enables you to register, create a personal profile, and customize use of the site's tools and resources. NurseONE provides such services as the following:

- Professional links (resources with clinical or professional orientation)
- Professional development (including resources for continuing competence, online and continuing education, and career development)
- Library (access to numerous articles and publications)
- NurseConnect (use of the portal to create discussion groups among individual subscribers)

Resources available to subscribers also include conducting self-assessments, creating individualized learning plans, and developing an online professional portfolio. You can also track current news and nursing information, receive updates and alerts on items of interest, access educational opportunities, and search for practice support on the NurseONE site. This site will continue to develop over time and provides a centralized professional nursing forum for Canadian nurses.

Clinician Engagement and Informatics Communities

Many Canadian and international health informatics communities exist that offer exciting opportunities for participation: support, educational programs, and networking opportunities. Of most importance, these communities always welcome new members who are interested in advancing informatics. As noted throughout this chapter, involving clinicians in the selection, design, and revision of technology is critically important. As a professional, you have both an obligation and a right to be involved in issues that affect your professional practice and your work environment.

Many informatics organizations have specific strategies to foster clinician engagement or encourage clinicians to become involved; however, literature on the topic of clinician engagement is scarce. Mercer (2008) promoted involvement through five questions (the “5 Ws”): (1) What is it? (2) Who should be involved? (3) Why is it important? (4) Where does it fit? and (5) When should clinicians get involved? Mercer advocated immediate involvement in any clinical environment.

The CNA is the national professional body representing Canadian nurses. The CNA's mandate of supporting professional nursing practice also includes supporting the integration of nursing informatics in Canada. The CNA has issued many position statements and professional guidelines to support all nurses as technology has become increasingly integrated into Canadian practice environments. The CNA provides an excellent starting point from which you can explore nursing informatics in Canada.

The **Canadian Nursing Informatics Association (CNIA)** is the national special interest group dedicated to the advancement of nursing informatics in Canada (Box 16-6). CNIA is designated as a group affiliated with the CNA. Also affiliated with COACH, CNIA is the Canadian nursing representative to the **International Medical Informatics Association–Special Interest Group in Nursing Informatics (IMIA–SIGNI)**. Originally functioning as a special-interest group within COACH,

► BOX 16-6

Getting to Know Your Canadian Nursing Informatics Association

The mission of the CNIA is to enable the improvement of nursing through the use of evidence-based practice using nursing informatics, information technology, and information management.

The goals of this national organization include the following:

1. Influence and advance the use of nursing informatics and nursing data standards.
2. Connect nurses and health providers across the country for the purpose of improving best practice.
3. Support nurses in practice and education by providing resources for the advancement of nursing informatics competencies via training, tool kits, standards, and communities of practice.
4. Establish best practices in clinical information technology (IT) and information management.

Membership offers benefits such as access to a network of national nursing informatics experts and communication forums, valuable educational opportunities and conference events, and the ability to contribute to national discussions shaping the nursing informatics space. Find out more about CNIA at <http://cnia.ca/>.

Source: Canadian Nursing Informatics Association. (2011). *2011 strategic plan*. Toronto: Author.

this group disbanded in 2000 and resumed as the CNIA (CNIA, 2000). This group has agreed to include the following mandates:

- To provide nursing leadership for the development of nursing and health informatics in Canada
- To establish national networking opportunities for nurse informaticians
- To facilitate informatics educational opportunities for all nurses in Canada
- To engage in international NI initiatives
- To act as a nursing advisory group in matters of nursing and health informatics

Since being founded, the CNIA has hosted successful national NI conferences, launched a national online journal (*Canadian Journal of Nursing Informatics*), provided educational offerings, and advocated for the advancement of NI in Canada. CNIA continues to evolve, incorporating a new journal club and new initiatives supporting nurses' continuing education opportunities.

In 2011, Canada Health Infoway launched a new initiative with the CASN, designed to integrate informatics competencies into nursing curricula across Canada. Additionally, Infoway hosts a Clinician Peer Network to foster greater knowledge and adoption among clinicians.

As noted earlier in this chapter, COACH is another organization dedicated to promoting health informatics within the Canadian health system through education, information, networking, and communication. COACH was formed in 1975 by software developers and health care clinicians (COACH, 2011). Their original focus was to support effective use of information technology and systems among Canadian health institutions by sharing ideas and efforts. This focus has expanded to include the effective use of health information for decision making.

COACH's multidisciplinary membership encompasses more than 1300 individuals, including health care executives, physicians, nurses and allied health professionals, researchers

and educators, chief information officers, information managers, technical experts, consultants, and information technology vendors (COACH, 2011). Member organizations include health care service deliverers, government and nongovernment agencies, consulting firms, commercial providers of information and telecommunications technologies, and educational institutions.

In addition to the previous groups, you can also contribute your clinician perspective to the various Standards Collaborative Working Groups (SCWGs) sponsored by Infoway. These groups are open and voluntary in nature, which means that you need only express your interest to participate; you do not need to hold paid membership in the Standards Collaborative. You will be welcomed to any SCWG groups; however, most nurses will find that the Public Health (SCWG 1), Individual Care (SCWG 2), and Terminology (SCWG 9) SCWGs will reflect their professional areas of interest. Participating in these SCWGs not only supports your professional practice but also offers you an opportunity for professional development and mentoring. Many experienced nurses are currently involved in advisory groups of the Standards Collaborative, but the SCWGs consistently need and solicit clinician engagement. You can access the SCWGs at the following URL: <https://www.infoway-inforoute.ca/forums>.

You can also choose to participate in a variety of international informatics organizations. These include the **American Medical Informatics Association (AMIA)**, the **International Medical Informatics Association (IMIA)**, and the **Health Informatics Society of Australia (HISA)**, all of which host special-interest groups in NI. You can be involved at every level of information management in health care. Your challenge and opportunity is to decide where your interest and energy can be best used.

In addition to the formal organizations that you may consider joining, numerous informal communities are devoted to NI and creating dialogue among nurses. You may decide to explore a variety of informal communities or social entities, including the following:

- **Blogs:** These are online diaries generally sponsored by individuals, which are occasionally interactive but typically present only the thoughts and opinions of the blog's sponsor.
- **Wikis:** These are Web pages that are interactive and allow subscribers to modify or contribute to the content. Subscribers are able to use any Web browser. Wikis also allows users to incorporate hyperlinks and use a simplified language to create new pages and linkages rapidly.
- **Listserv and discussion groups:** These are e-mail distribution lists. NI sites allow and encourage you to subscribe to the listserv or discussion groups so you can receive regular contact and updates in regard to content, activities, or networking opportunities. These tools also allow you to ask question, post messages, and network with colleagues
- **Social media:** Communities such as Facebook or Twitter allow subscribers to join or follow groups who are interested in shared interests and activities. These Web-based communities include a variety of ways in which subscribers may communicate, such as chat, messaging, e-mail, blogs, video, voice chat, file sharing, discussion groups, and message boards. Interest groups and organizations are regularly using these types of social media tools to create communities of practice and share experiences. Nurses who use these tools must do so in a fashion consistent with the ethical practice of nursing and privacy legislation.

The value of interest in informal networking cannot be underestimated; however, you should not depend on these types of forums for consistent, professional, and credible health informatics information. Some sites may offer highly professional informatics advice or information; unfortunately, no standards exist with regard to either content or process. Many sites offer only personal or anecdotal commentary and may provide misleading information, which can create liability if used in your professional practice. Consequently, you must critically evaluate the content of these informal sites and groups to determine the validity of the content, the credibility of the organization or group, and the intent of the networking tool. The most effective way to obtain reliable and authoritative information is through formalized organizations that are committed to the professional advancement of informatics.

✦ CRITICAL THINKING EXERCISES

1. You have been assigned to lead a team tasked with implementing a standardized nursing terminology for your hospital. What critical topics would you assign your team for review? What groups would you connect with to initiate discussions on best practices? What would be the top four activities to proceed with this task?
2. During the course of documenting an admission assessment, you note that your patient has had a previous admission to a psychiatric unit. One of your colleagues is a neighbour of the patient and asks you to confirm whether this patient has a psychiatric history. Your colleague is not providing care to the patient. How do you respond to this inquiry? What pieces of legislation do you consider in helping you come to a decision?

✦ REVIEW QUESTIONS

1. Changes that occurred in the health care system over the last few decades that have contributed to the recognition of NI include
 1. Decreasing technology in health care and the evolution toward evidence-informed practice
 2. Requests for nursing informatics from administrators and national databases
 3. A recognition among nurses that specific nursing data must be documented consistently in order to create high-quality health data, support evidence-informed decision making, and represent nursing contributions
 4. Competition among professions to lead technology adoption
2. The factors behind the need for standardized nursing documentation include which of the following?
 1. To facilitate aggregation of nursing data, and support data analysis
 2. To enhance communication among nurses
 3. To improve representation regarding nursing contributions
 4. All of the above
3. Identify which of the following standardized nursing terminology is being used in Canada.
 1. interRAI
 2. ICNP®
 3. SNOMED CT®
 4. HOBIC

4. Select which of the following privacy legislation influences nursing practice in Canada.
 1. PIPEDA and the *Privacy Act*
 2. PIPEDA and SCWGs
 3. Standards Collaborative Working Groups (SCWG) and Standards
 4. *Privacy Act* and *Code of Ethics*
5. How can you, as a nurse, enact the *e-Nursing Strategy*?
 1. Buy your own laptop, and design a nursing-related website
 2. Complete mandatory education on your hospital information system
 3. Support access to technology for all nurses, develop your technology competencies, and participate in advancing ICT and NI
 4. Work at the Canadian Nurses Association
6. What nursing or health informatics communities are available to nurses?
 1. CNIA, IMIA-SIGNI
 2. CNA, CMA
 3. HOBIC, TTYL
 4. CSA, ICD-10

Communication

Written by Sonya L. Jakubec, RN, MN, PhD(c), and Barbara J. Astle, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Describe aspects of critical thinking that are important to the communication process.
- Describe the five levels of communication and their uses in nursing.
- Describe the basic elements of the communication process.
- Discuss the role of communication in relational practice.
- Identify the communication skills important for relational practice.
- Identify significant features and therapeutic outcomes of nurse–patient helping relationships.
- List nursing focus areas within the four phases of a nurse–patient helping relationship.
- Identify significant features and desired outcomes of nurse–health care team member relationships.
- Describe qualities, behaviours, and communication techniques that affect professional communication.
- Discuss effective communication techniques for patients at various developmental levels.
- Identify patient health states and conditions that contribute to impaired communication.
- Discuss nursing care measures for patients with special communication needs.

Communication is a lifelong learning process for the nurse. Nurses are intimately involved with patients and their families from birth to death. It is important to build therapeutic communications for this journey. Nurses should communicate effectively with people who are in stressful circumstances. They function as patient advocates and as members of interprofessional teams, other members of which often have different priorities for patient care. Nurses also have to communicate their own needs to avoid burnout and to continue providing effective care (Balzer Riley, 2008). Despite the competing demands on nurses' time and current technological complexity, it is the intimate nurse–patient

connection that makes the difference in the quality of care and in the meaning of the illness experience for both (Balzer Riley, 2008). Therefore, competency in a variety of communication techniques supports the nurses' ability to develop and maintain therapeutic relationships. Effective communication promotes collaboration and interdisciplinary teamwork, helps ensure that ethical and legal responsibilities and professional practice standards are met, and contributes to positive patient outcomes (Apker et al., 2006). Ineffective communication may lead to poor patient outcomes, increases in adverse incidents, and decreases in professional credibility. The Conference Board of Canada considers communication and interpersonal relationship skills to be crucial for successful employment and the establishment of healthy work environments (Devito et al., 2011).

The qualities, behaviours, and therapeutic communication techniques described in this chapter characterize professionalism in helping relationships. Although the term *patient* is often used, the same principles can be applied in communicating with any person, group, or population in any nursing situation.

Communication and Interpersonal Relationships

At the core of nursing care are therapeutic interpersonal relationships based on caring, mutual respect, and dignity. Communication is the means to establish these helping-healing relationships. As all behaviour communicates, and all communication influences behaviour, nurses must become experts in communication if they are to provide effective care.

The nurse's capacity to be in relation with other people—to take initiative in establishing and maintaining a relationship, to be authentic and responsive to the other person—is a crucial aspect of interpersonal communication. The will and active intention of nurses to join people where they are is what is meant by initiative in **relational communication**. Reaching out and listening are parts of taking **initiative**. Being spontaneous and genuine, aware of the in-the-moment experiences of the patient and one's self, are aspects of **authenticity**. Authenticity is often one of the characteristics of nurses that imbues the trust of the public. Hartrick Doane & Varcoe (2005) explain that "when a nurse has the initiative to be with another in an authentic way, she or he is able to respond to the other as they are in that moment" (p. 193). Effective interpersonal communication also requires a sense of **mutuality** and being in a mutual relation. Being "in synch" in this way is based on a belief that the nurse–patient relationship is a partnership and that both partners are equal participants. Mutuality requires that both participants respect each other's autonomy and value system and are committed to the patient's well-being (Arnold & Boggs, 2011). In their work, nurses honour the fact that people are complex and ambiguous beings. Often, more is communicated than is initially apparent, and patient responses are not always what you might expect. **Questioning beyond the surface** is a skill that nurses employ that facilitates relationships within complex circumstances of health and illness. Nurses are further able to engage with ambiguity and complexity and expand their capacity to communicate by focusing on their relational capacity and skills of:

- Letting be
- Listening
- Self-observation

- Questioning to look beyond the surface
- Intentionality
- Interrupting contextual constraints
- Reimagining (Hartrick Doane & Varcoe, 2005)

Other perspectives of communication and relationships draw upon notions of balance (Hunter et al., 2006) and energy fields (Guelnder et al., 2005) as aspects of communication that permeate and connect all beings. Although the use of energy and nature to heal is a relatively new concept in Western cultures, it has long existed in Aboriginal and Eastern cultures. Most nurses embrace the profession's view of people as holistic beings and have experienced synergy in human interactions.

Therapeutic communication occurs within a healing environment between a nurse and a patient (Arnold & Boggs, 2011). While their very words are medicine or poison, nurses also know that attitudes and emotions are easily transmitted and can be communicated intentionally or unintentionally. Every nuance of posture, every small expression and gesture, every word chosen, every attitude held—all have the potential to hurt or heal. Because thought patterns (positive or negative), intention, and behaviour directly influence human energy fields and therefore health, nurses have a tremendous ethical responsibility to pay careful attention to their communication with patients. Communication must be respected for its potential power and not carelessly misused to hurt, manipulate, or coerce patients. Good communication empowers patients and enables them to know themselves and make their own choices, which is an essential aspect of the healing process. Nurses have the opportunity to create positive outcomes for themselves, patients, and colleagues through therapeutic communication.

Developing Communication Skills

Gaining expertise in communication requires an understanding of the communication process, commitment to an evolving capacity to be in relation to others, and in-depth reflection about personal communication experiences (Balzer Riley, 2008). In addition, the qualities of good critical thinking and problem solving are important to the communication process. Curiosity, perseverance, creativity, self-confidence, independence, fairness, integrity, and humility are useful in approaching a problem (see Chapter 11).

Interpersonal communication may be challenging because it is based on an individual's perception of received information and is therefore subject to misinterpretation. **Perception** is based on information acquired through the five senses of sight, hearing, taste, touch, and smell (Austin & Boyd, 2010). It is a process of mentally organizing and interpreting sensory information to arrive at a meaningful conclusion. An individual's culture, education, and personal background also influence perception (see Chapter 9). Critical thinking and self-reflection can help nurses overcome **perceptual biases**, which are human tendencies that interfere with accurately perceiving and interpreting messages from other people. People often assume that others would think, feel, act, react, and behave as they themselves would in similar circumstances. People tend to distort or ignore information that goes against their expectations, preconceptions, or stereotypes (Beebe et al., 2011). By thinking critically about personal communication habits, you will gain awareness of these tendencies and become more responsive to your patients and your goals of therapeutic communication.

► BOX 17-1

Communication Throughout the Nursing Process

Assessment

Verbal interviewing and history taking
 Visual and intuitive observation of nonverbal behaviour
 Documentation of visual, tactile, and auditory data during physical examination
 Written medical records, diagnostic test results, and literature review

Nursing Diagnosis

Intrapersonal analysis of assessment findings
 Validation of health care needs and priorities through verbal discussion with patient
 Handwritten or electronic documentation of nursing diagnosis

Planning

Interpersonal or small-group planning sessions with health care team
 Interpersonal collaboration with patient and family to determine implementation methods
 Written documentation of expected outcomes
 Written or verbal referral to members of the health care team

Implementation

Delegation and verbal discussion with health care team
 Verbal, visual, auditory, and tactile health teaching activities
 Provision of support through therapeutic communication techniques
 Contact with other health care resources and the interprofessional team
 Written documentation of patient's progress in medical record
 Communicating targeted, effective public and population health messages

Evaluation

Acquisition of verbal and nonverbal feedback
 Comparison of actual and expected outcomes
 Identification of factors affecting outcomes
 Modification and update of care plan
 Verbal or written explanation, or both, of revisions of care plan to patient
 Receiving and responding to feedback about one's own nursing care

As communication skills develop, competence in the nursing process occurs. Integration of communication skills throughout the nursing process facilitates collaboration with patients and members of the interprofessional team (Box 17-1). Communication skills are used to gather, analyze, and transmit information and to accomplish the work of each step of the process. Assessment, diagnosis, planning, implementation, and evaluation all depend on effective communication among nurse, patient, family, and other members of the interprofessional team. Although the nursing process is a reliable framework for patient care, it does not work well unless you master the art of effective interpersonal communication.

The nature of the communication process requires nurses to constantly make decisions about what, when, where, why, and how to convey messages to other people. Decision making is always contextual; unique features of any situation influence the nature of the decisions made. For example, the importance of following a prescribed diet will be explained differently to a patient with a newly diagnosed medical condition than to a patient who has repeatedly chosen not to follow diet restrictions. In nursing communication, **seeking**

► BOX 17-2

Challenging Communication Styles of Patients

- Silent, withdrawn; do not express any feelings or needs
- Sad, depressed; have slow mental and motor responses
- Angry, hostile; do not listen to explanations
- Uncooperative; resent being asked to do something
- Talkative, lonely; want someone with them all the time
- Demanding; want someone to wait on them or meet their requests
- Ranting and raving; blame nursing staff unfairly for their misfortunes or difficulties
- Sensory impaired; cannot hear or see well
- Verbally impaired; cannot articulate needs or desires
- Gossiping; violate confidentiality and cause friction
- Mentally handicapped; are frightened and distrustful
- Confused, disoriented; are bewildered and uncooperative
- Foreign-born; speak very little of the dominant culture's language
- Anxious, nervous; cannot cope with what is happening
- Grieving, crying; have sustained a major loss
- Screaming, kicking (toddlers); want their parents
- Flirtatious, sexually inappropriate
- Loud, obscene; cause disturbances or violate rules

contextual knowledge is the building block to providing context-based and relevant care (Hartrick Doane & Varcoe, 2005). Effective communication skills such as “seeking contextual knowledge” are easy to learn, but their application is more difficult and nuanced. Deciding which approach is most responsive to each unique nursing situation is challenging and requires tremendous self-awareness and reflexivity. **Reflexivity** is being aware of your own patterns of communication and own response to communication as well as the responses you are evoking in others. When considering self-awareness, imagine how communication about specific diagnoses such as cancer or end-of-life conditions and dealing with patient and family emotions might be challenging to you. Certainly, some nurses struggle to cope with their own reactions and emotions when communicating difficult news to families and patients (Sheldon et al., 2006).

Throughout this chapter, brief clinical examples guide you in the use of effective communication techniques. Styles of patients that commonly challenge nurses' decision making and communication are described in Box 17-2. Because the best way to acquire skill is through practice, it is useful for you to know yourself and your own personal styles, as well as typical responses to situations. Discussing and role playing these scenarios before experiencing them in the clinical setting may be helpful.

Levels of Communication

Nurses use different levels of communication in their professional role: intrapersonal, interpersonal, transpersonal, small-group, and public.

Intrapersonal Communication

Intrapersonal communication, exemplified in one's thinking, is also known as *self-talk* or *inner thought*. It is a powerful form of communication that occurs *within* an individual (Beebe et al., 2011). Nurses and patients use intrapersonal communication to develop self-awareness and a positive

self-concept that can facilitate self-expression and improve health and self-esteem by replacing negative thoughts with positive assertions.

Interpersonal Communication

Interpersonal communication is the one-to-one interaction between the nurse and patient that often occurs face to face. It is the level most frequently used in nursing practice. It takes place within a social context and includes all the symbols and cues used to give and receive meaning.

Sometimes messages are received differently than the messenger intended. Nurses work with people who have different opinions, experiences, values, and belief systems; therefore, meaning must be validated or mutually negotiated between participants.

Transpersonal Communication

Transpersonal communication occurs within a person's spiritual domain. Nurses are able to communicate and relate to their patients within this domain (see Chapter 27). **Spiritual inquiry** is an approach to communication whereby nurses can join with their patients to create a road map of what is meaningful, significant, and important for the patient in their unique context. This inquiry illuminates the patient's contexts, understandings, experiences, and hopes. It is through such dialogue that nurses can communicate with patients in times of deeper, often complex, conflicted, and ambiguous situations (Hartrick Doane & Varcoe, 2005).

Small-Group Communication

Small-group communication is interaction that occurs when a small number of people meet together and share a common purpose. This type of communication is usually goal-directed and requires an understanding of group dynamics. When nurses work on committees, lead patient support groups, form research teams, or participate in patient care conferences, they are using the small-group communication process. For small groups to function effectively, members must feel accepted, comfortable in sharing ideas and thoughts openly and honestly, and able to actively listen to other group members and consider possible alternative viewpoints (Arnold & Boggs, 2011).

Public Communication

Public communication is interaction with an audience. Nurses have opportunities to speak with groups of consumers about health-related topics, present scholarly work to colleagues at conferences, lead classroom discussions with peers or students, or engage in public advocacy or media activities. Public communication requires special adaptations in eye contact, gestures, and voice inflection and the use of media materials to communicate messages effectively. The purpose of public communication by nurses is to increase audience knowledge about health-related topics, health care issues, and other issues important to the nursing profession.

Basic Elements of the Communication Process

Communication is an ongoing, dynamic, and multidimensional process. Its basic elements are illustrated in Figure 17-1 and described in the following paragraphs. This simple model represents what is, in practice, a very complex process. The model helps identify essential components of communication.

Figure 17-1 Communication is an active process between sender and receiver.

Referent

The **referent** motivates one person to communicate with another. In a health care setting, sights, sounds, odours, time schedules, messages, objects, emotions, sensations, perceptions, ideas, and other cues trigger communication. When a nurse knows the stimulus that triggered communication she or he is able to develop and organize messages for effective communication.

Sender and Receiver

The **sender** is the person who encodes and delivers the message, and the **receiver** is the person who receives and decodes the message. The sender puts ideas or feelings into a form that can be transmitted and is responsible for accuracy and emotional tone. The sender's message acts as a referent for the receiver, who is responsible for attending to, decoding, and responding to the sender's message. Sender and receiver roles are fluid and change back and forth as people interact; sometimes sending and receiving even occur simultaneously. The more the sender and receiver have in common and the closer their relationship, the more likely they will accurately perceive one another's meaning and respond accordingly.

Messages

The **message** is the content of the communication. It contains verbal, nonverbal, and symbolic expressions of thoughts or feelings that are transmitted from the sender to the receiver (Arnold & Boggs, 2011). Personal perceptions sometimes distort the receiver's interpretation of the message. Two nurses can provide the same information and yet convey very different messages according to their personal communication styles. One nurse can send the same message to two people and be understood differently by each. You can send effective messages by expressing yourself clearly, directly, and in a manner familiar to the receiver. By watching the listener for nonverbal cues that suggest confusion or misunderstanding,

you can determine whether the message needs to be clarified. Communication can be difficult when participants have different levels of education and experience. “Your incision is well approximated without purulent drainage” means the same as “Your wound edges are together, with no signs of infection,” but the latter is easier to understand. You must be sure patients are able to read before you send messages in writing.

Channels

Channels are means of conveying and receiving messages through visual, auditory, and tactile senses. Facial expressions send visual messages, spoken words travel through auditory channels, and touch traverses tactile channels. The more channels the sender uses to convey a message, the more clearly the message is usually understood. For example, when teaching about insulin self-injection, the nurse talks about and demonstrates the technique, gives the patient printed information, and encourages hands-on practice with the vial and syringe. Nurses use verbal, nonverbal, and mediated (technological) communication channels. They send and receive information in person; by informal or formal writing; over the telephone or pager; by audio and video recording; and through fax, e-mail, and interactive electronic or social networking media.

Feedback

Feedback is the message returned by the receiver. It indicates whether the meaning of the sender’s message was understood by the receiver. Senders need to seek verbal and nonverbal feedback to ensure that clear communication has occurred. To be effective, the sender and receiver must be sensitive and open to each other’s messages, clarify the messages, and modify behaviour accordingly. In a social relationship, both participants assume equal responsibility for seeking openness and clarification, but in the nurse–patient relationship, this responsibility is primarily the nurse’s.

Interpersonal Variables

Interpersonal variables are characteristics within both the sender and receiver that influence communication. People perceive events differently (Austin & Boyd, 2010). A nurse might say, “You have been very quiet since your family left. Is something on your mind?” One patient might perceive the nurse’s question as showing caring and concern; another might perceive the nurse as being intrusive. It is the responsibility of the nurse to seek out the variables and contexts that will communicate sensitively and effectively. Other interpersonal variables include educational and developmental levels, sociocultural backgrounds, values and beliefs, emotions, gender, physical health status, and roles and relationships. Variables associated with illness, such as pain, anxiety, and medication effects, can also affect nurse–patient communication and should all be considered in communication choices (Feldman-Stewart et al., 2005).

Environment

The **environment** is the setting for sender–receiver interaction. For effective communication, the environment should meet nurse and patient needs for physical and emotional comfort and safety. Noise, temperature extremes, distractions, and lack of privacy or space create confusion, tension, and discomfort. Environmental distractions are common in health care settings and interfere with messages sent between people. Establishing as comfortable an environment as possible to

create favourable conditions for effective communication is a role of the nurse.

Forms of Communication

Messages are conveyed verbally, nonverbally, concretely, and symbolically. As people communicate, they express themselves through words, movements, voice inflection, facial expressions, and use of space. These elements work in harmony to enhance a message and can also conflict with one another to contradict or confuse the message.

Verbal Communication

Verbal communication entails the use of spoken or written words. Verbal language is a code that conveys specific meaning through a combination of words. The most important aspects of verbal communication follow.

Vocabulary. Communication is unsuccessful if senders and receivers cannot decode each other’s words and phrases. When a nurse cares for a patient who speaks another language, the services of an interpreter may be necessary. Even those who speak the same language use subcultural variations of certain words: *dinner* may mean a noon meal to one person and the last meal of the day to another. Medical jargon (technical terminology used by the interprofessional team) may sound like a foreign language to patients and should be used only with other members of the interprofessional team. Children have more limited vocabularies than do adults and may use special words to describe bodily functions or a favourite blanket or toy. Teenagers often use words in unique ways that are unfamiliar to adults.

Denotative and Connotative Meaning. A single word can have several meanings. Individuals who use a common language share the denotative meaning: *baseball* has the same meaning for everyone who speaks English, but *code* denotes cardiac arrest to health care providers. The connotative meaning is the interpretation of a word’s meaning influenced by the thoughts, feelings, or ideas that people have about the word. Families who are told that a loved one is “in serious condition” may believe that death is near, but to the nurse *serious* may simply describe the nature of the condition. You need to select words carefully, avoiding terms that can be easily misinterpreted, especially when explaining a patient’s medical condition or therapy. Even a much-used phrase such as “I’m going to take your vital signs” can be unfamiliar to an adult or frightening to a child.

Pacing. Messages are conveyed more successfully when sent at an appropriate speed or pace. Speak slowly enough to enunciate clearly. Talking rapidly, using awkward pauses, or speaking slowly and deliberately can convey an unintended message. Long pauses and rapid shifts to another topic may be unsettling for a patient. Pacing is improved by thinking before speaking and by developing awareness of the cadence of your speech.

Intonation. Tone of voice dramatically affects the meaning of a message. Depending on intonation, even a simple question or statement can express enthusiasm, anger, concern, or indifference. To avoid sending unintended messages, be aware of your tone of voice. For example, patients may interpret a nurse’s tone of voice as condescending, and further communication may be inhibited. A patient’s tone of voice is also highly relevant to communication and may provide information about his or her emotional state or energy level.

Clarity and Brevity. Effective communication is simple, brief, and direct. Fewer words result in less confusion. You achieve clarity by speaking slowly, enunciating clearly, and using examples to make explanations easier to understand. Repeating important parts of a message also clarifies communication. Phrases such as “you know” or “okay?” at the end of every sentence detract from clarity, as well as professionalism. Brevity is achieved by using short sentences and words that express an idea simply and directly. “Where is your pain?” is much better than “I would like you to describe for me the location of your discomfort.”

Timing and Relevance. Timing is critical in communication. Even though a message is clear, poor timing can limit its effectiveness. For example, you should not begin routine teaching when a patient is in severe pain, is in emotional distress, or is distracted by pressing matters. Often the best time for interaction is when a patient expresses an interest in communicating. If messages are relevant or important to the situation at hand, communication is more effective. For example, when a patient is facing emergency surgery, discussing the risks of smoking is less relevant than explaining preoperative procedures.

Nonverbal Communication

Nonverbal communication makes use of all five senses and refers to transmission of messages that do not involve the spoken or written word. Researchers have estimated that approximately 7% of meaning is transmitted by words, 38% by vocal cues, and 55% by nonverbal body cues. Nonverbal communication serves to accent, complement, contradict, regulate, repeat, or substitute for verbal messages (Devito et al., 2011). Nonverbal communication is unconsciously motivated and therefore reflects a person’s intended meaning more accurately than spoken words (Austin & Boyd, 2010). When verbal and nonverbal communication are incongruous, the receiver usually “hears” the nonverbal message as the true message.

All kinds of nonverbal communication are important, but interpreting them is often difficult. Sociocultural background is a major influence on the meaning of nonverbal behaviour. Nonverbal messages between people of different cultures are easily misinterpreted. Because the interpretation of nonverbal behaviour is subjective, it is important to check its perceived meaning (Adler et al., 2008). Assessing nonverbal messages is an important communication skill that is highly consequential to patient assessment and nursing care (Austin & Boyd, 2010).

Personal Appearance. Personal appearance includes physical characteristics, facial expression, manner of dress and grooming, and adornments. These factors help communicate physical well-being, personality, social status, occupation, religion, culture, and self-concept. First impressions are largely based on appearance. Nurses learn to develop a general impression of patient health and emotional status through appearance, and patients develop a general impression of the nurse’s professionalism and caring in the same way.

Posture and Gait. Posture and gait are forms of self-expression. The ways that people sit, stand, and move reflect attitudes, emotions, self-concept, and health status. For example, an erect posture and a quick, purposeful gait communicate a sense of well-being and confidence. Leaning forward conveys attention. A slumped posture and a slow, shuffling gait may be indicative of depression, illness, discomfort, or fatigue.

Facial Expression. The face is the most expressive part of the body. Facial expressions convey emotions such as surprise, fear, anger, happiness, and sadness. Some people have an expressionless face, or flat affect, which reveals little about what they are thinking or feeling. An incongruent affect is a facial expression that does not match the content of a verbal message: for example, smiling when describing a sad situation. People are sometimes unaware of the messages their expressions convey. For example, a nurse may frown in concentration while doing a procedure and the patient may interpret this as anger or disapproval. Patients closely observe nurses. Consider the impact a nurse’s facial expression might have on a person who asks, “Am I going to die?” The slightest change in the eyes, lips, or facial muscles will reveal the nurse’s feelings. Although it is hard to control all facial expression, try to avoid showing shock, disgust, dismay, or other distressing reactions in the patient’s presence.

Eye Contact. People signal readiness to communicate through eye contact. Among many European and American people, maintaining eye contact during conversation shows respect and willingness to listen. Eye contact also allows people to closely observe one another. Lack of eye contact may indicate anxiety, defensiveness, discomfort, or lack of confidence in communicating. However, among some Asian and Aboriginal people, eye contact may be considered intrusive, threatening, or harmful. Eye movements can also communicate feelings and emotions. Standing above a person (looking downward) conveys authority, whereas interacting at the same eye level indicates equality in the relationship. Rising to the same eye level as an angry person communicates self-assertion.

Gestures. Gestures emphasize, punctuate, and clarify the spoken word, and may communicate volumes when speech is not possible. Gestures alone carry specific meanings and create messages. A finger pointed toward a person may communicate several meanings, but when accompanied by a frown and stern voice, the gesture conveys an accusation or a threat. Pointing to an area of pain may be more accurate than verbally describing the location.

Sounds. Sounds such as sighs, moans, groans, or sobs also communicate feelings and thoughts. When combined with other nonverbal communication, sounds help send messages. Sounds can be interpreted in several ways: sighing often suggests boredom or anxiety, moaning may convey pleasure or suffering, and crying may communicate happiness, sadness, or anger. You need to validate such nonverbal messages with the patient in order to interpret them accurately. Simply noticing the sound, such as stating “I hear you sighing so strongly” can impart concern and listening to what is not spoken.

Personal Space. Personal space is the need to gain, maintain, and defend one’s right to their space. Personal space is important because it provides people with a sense of identity, security, and control. Personal space can be distinguished and made visible to other people, as with a fence around a yard or a curtain around a bed in a hospital room. Personal space, however, is invisible and individual, connoting boundaries beyond the physical territory. Boundaries such as physical or emotional space can be defended just like another sort of fence or barrier. Some people choose when to open the gate of a fence, and others simply leave the boundary wide open, taking whatever comes through. When personal space becomes threatened, people respond defensively and communicate less effectively. Specific contexts may dictate whether the physical

or emotional distance between nurse and patient is appropriate. Because of the nature of caregiving, nurses often must move into a patient's personal space, even entering a more vulnerable zone in that personal space. For instance, when conducting an in-depth patient assessment or performing an intervention such as wound care, there is necessarily close personal and emotional contact between nurse and patient. Before entering into a patient's personal space, it is essential that you prepare both your patient and the environment. By explaining to your patient what you will do and preparing the environment for particular nursing interventions, your patient will recognize a shift toward the establishment of a therapeutic interaction. You need to convey confidence, gentleness, and respect for privacy, especially when your actions will require intimate contact or involve a patient's vulnerable zone. Box 17-3 provides examples of nursing actions within zones of personal space (Austin & Boyd, 2010) and zones of touch.

Symbolic Communication

Good communication requires awareness of **symbolic communication**, the verbal and nonverbal symbolism used to convey meaning. Art and music are forms of symbolic communication that nurses use to enhance understanding and promote healing. Lane (2006, 2008) found that creative expressions such as art, music, and dance have a healing effect on

patients. Patients reported decreased pain and greater joy and hope, and were often more open to communication when creative expressions were part of therapeutic communication.

Metacommunication

Metacommunication is a broad term that refers to all factors that influence how a message is perceived by other people (Arnold & Boggs, 2011). It is communication *about* communication (Devito et al., 2011) that reflects the relational aspects of messages (Adler et al., 2008) and helps people better understand what has been communicated. For example, a nurse observes a young patient holding his body rigidly erect, and his voice is sharp as he says, "Going to surgery is no big deal." The nurse replies, "You say having surgery doesn't bother you, but you look and sound tense. I'd like to help." Awareness of the tone of the verbal response and the nonverbal behaviour may result in further exploration of the patient's feelings and concerns.

Professional Nursing Relationships

The nurse's application of knowledge, understanding of human behaviour and communication, and commitment to ethical behaviour all contribute to the formation of professional relationships. The intention to promote caring and respect for other people will help you be more successful in establishing professional relationships.

Nurse-Patient Helping Relationships

Helping relationships are the foundation of clinical nursing practice. In such relationships, the nurse assumes the role of professional helper and comes to know the patient as an individual who has unique health care needs, human responses, and patterns of living. The relationship is therapeutic, promoting a psychological climate that facilitates positive change and growth. Therapeutic communication allows patients to achieve their health care-related goals and attain optimal personal growth (Arnold & Boggs, 2011). It includes an explicit time frame and a goal-directed approach, and confidentiality is an expected feature. The nurse establishes, directs, and takes responsibility for the interaction, and the patient's needs take priority over the nurse's needs. The relationship is also characterized by the nurse's nonjudgemental acceptance of the patient. Acceptance conveys a willingness to hear a message or to acknowledge feelings. It does not mean you always agree with the patient or approve of the patient's decisions or actions. A helping relationship between nurse and patient does not just happen; you create it through care, skill, and the development of trust.

The nurse-patient helping relationship is characterized by a natural progression of four goal-directed phases: preinteraction, orientation, working, and termination phases (Box 17-4). These phases often begin before the nurse meets the patient and continue until the caregiving relationship ends. Even a brief interaction is characterized by an abbreviated version of these four phases. For example, the student nurse gathers patient information to prepare in advance for caregiving, meets the patient and establishes trust, accomplishes health care-related goals through use of the nursing care process, and says goodbye at the end of the shift or when the patient leaves the unit.

Socializing is an important initial component of interpersonal communication. It helps people get to know one another

► BOX 17-3 Zones of Personal Space and Touch

Zones of Personal Space

Intimate Zone (0 to 45 cm)

Holding a crying infant
Performing physical assessment
Bathing, grooming, dressing, feeding, and toileting a patient
Changing a patient's dressing

Personal Zone (45 cm to 1 m)

Sitting at a patient's bedside
Taking the patient's health history
Teaching an individual patient
Exchanging information with health care staff at change of shift

Social Zone (1 to 4 m)

Participating in patient care rounds
Sitting at the head of a conference table
Teaching a class for patients with a specific disease
Conducting a family support group session

Public Zone (4 m and greater)

Speaking at a community forum
Testifying at a legislative hearing
Lecturing to a class of students

Zones of Touch

Social Zone (assess for permission to touch)

Hands, arms, shoulders, back

Consent Zone (consent needed)

Mouth, wrists, feet

Vulnerable Zone (consent and special care needed)

Face, neck, front of body

Intimate Zone (consent and great sensitivity needed)

Genitalia, rectum

► BOX 17-4 Phases of the Helping Relationship

Pre-Interaction Phase

Before meeting the patient, the nurse accomplishes the following tasks:

- Reviews available data, including the medical and nursing history
- Talks to other caregivers who may have information about the patient
- Anticipates health care concerns or issues that may arise
- Identifies a location and setting that will foster comfortable, private interaction with the patient
- Plans enough time for the initial interaction

Orientation Phase

When the nurse and patient meet and get to know one another, the nurse accomplishes the following tasks:

- Sets the tone for the relationship by adopting a warm, empathetic, caring manner
- Recognizes that the initial relationship may be superficial, uncertain, and tentative
- Expects the patient to test the nurse's competence and commitment
- Closely observes the patient and expects to be closely observed by the patient
- Begins to make inferences and form judgements about patient messages and behaviours
- Assesses the patient's health status
- Prioritizes the patient's problems and identifies the patient's goals
- Clarifies the patient's and nurse's roles
- Negotiates a contract with the patient that specifies who will do what
- Lets the patient know when to expect the relationship to be terminated

Working Phase

When the nurse and patient work together to solve problems and achieve goals, the nurse accomplishes the following tasks:

- Encourages and helps the patient to express feelings about his or her health
- Encourages and helps the patient to explore own feelings and thoughts
- Provides information that the patient needs to understand and change behaviour
- Encourages and helps the patient to set goals
- Takes actions to meet the goals set with the patient
- Uses therapeutic communication skills to facilitate successful interactions
- Uses appropriate self-disclosure and confrontation

Termination Phase

During the ending of the relationship, the nurse accomplishes the following tasks:

- Reminds the patient that relationship termination is near
- Evaluates goal achievement with the patient
- Reminisces about the relationship with the patient
- Separates from the patient by relinquishing responsibility for his or her care
- Facilitates a smooth transition for the patient to other caregivers as needed

* BOX 17-5

EVIDENCE-INFORMED PRACTICE GUIDELINE

Expanding Capacity for Positive Nurse–Patient Relationships Through Enhanced Communication Skills

Some students and nurses may claim: “I’m more technically inclined—communication and relationship skills are not really my strength.” While we all have particular strengths and weaknesses in our nursing practice, research shows us that, with skills, training, and practice, we can continue to enhance our capacity for communication with positive outcomes for our helping relationship and patient outcomes. Veronique Boscart, of the University of Toronto, conducted a study to evaluate the effect of a three-hour communication skills training session on the quality of verbal interactions between nursing staff and patients in a chronic care facility. Before the training, which included lecture, role playing, discussion, and reflection, the staff nurses in chronic care nursing practice were predominantly task-oriented and their style of communication was largely authoritative and advice giving in nature. Findings of the study revealed that, even several months following the training, with practice and attention on skills such as inquiry, listening, and validation, the positive qualities of nurse–patient interactions were greatly enhanced. Boscart’s study shows us that effective communication is something we can learn, and that with practice we can continue to expand our capacity for relational practice (Hartrick-Doane & Varcoe, 2005). Relational practice is an approach to communication that relies on the nurse’s capacity to be in relation to patients.

Source: Boscart, V. M. (2009). A communication intervention for nursing staff in chronic care. *Journal of Advanced Nursing*, 65(9), 1823–1832.

and relax. It is easy, superficial, and not deeply personal, whereas therapeutic interactions are often more difficult, intense, and uncomfortable. A nurse often uses social conversation to lay a foundation for a closer relationship: “Hi, Mr. Simpson. I hear it’s your birthday today. Happy birthday!” A friendly, informal, and warm communication style helps establish trust, but nurses must get beyond social conversation to talk about issues or concerns affecting the patient’s health. During social conversation, patients may ask personal questions about the nurse’s family, place of residence, and so forth. Students often wonder whether it is appropriate to reveal such information. The skillful nurse uses judgement about what to share and provides minimal information or deflects such questions with gentle humour and refocuses conversation back to the patient.

Creating a therapeutic environment depends on your ability to communicate, comfort, and help patients meet their needs. Comfort is crucial in the practice of nursing. Therapeutic interactions increase feelings of personal control by helping patients feel secure, informed, and valued. Optimizing personal control facilitates emotional comfort, which minimizes physical discomfort and promotes recovery (Boscart, 2009) (Box 17-5).

In a therapeutic relationship, nurses often encourage patients to share personal stories, which are called **narrative interactions**. Through narrative interactions, such as reminiscing with patients, you begin to understand the context of patients’ lives and learn what is meaningful from their

perspective (Shattell & Hogan, 2005). For example, a nurse asked a patient to tell about a time in his life when he had to make a difficult decision. The patient related the following story:

"When I was a young man, I worked on the family farm. An uncle died and left me some money. All of a sudden, I could afford to go to university, but Dad didn't want me to go because he needed me there. I had to decide whether to stay or go, and it was real hard because at first I just wanted to get away. I talked to our preacher, and he said it was up to me, to pray about it and do what my heart told me to. So I stayed. Oh, I've thought from time to time what I might have made of myself, but I never regretted it. I had a good life in farming."

From this brief story, the nurse understood that it was important to the patient to put his family's needs above his personal desires and that seeking spiritual guidance was an important component of his decision making. This same information may not have been revealed had the nurse used a standard history that usually elicits only short answers.

Collaboration between nurses and patients builds relationships and is based on principles of mutual gain and respect. It reflects a desire to satisfy the needs of both parties (Dubrin & Geerincx, 2009). **Collaborative communication** promotes personal responsibility, enables self-expression, and strengthens the patient's problem-solving ability. In addition to patient-nurse communication, nurses also communicate collaboratively with the interprofessional team. These skills are highly consequential to patient outcomes (Gottlieb & Feeley, 2006).

Nurse-Family Relationships

Many nursing situations, especially those in the community, require the nurse to form helping relationships with entire families. The same principles that guide one-to-one helping relationships also apply when the patient is a family unit; however, communication within families requires additional understanding of the complexities of family dynamics, needs, and relationships (see Chapter 19).

Interprofessional Team Relationships

Nurses function in roles that require interaction with interprofessional teams. Many elements of the nurse-patient helping relationship also apply to collegial relationships, which focus on accomplishing the work and goals of the clinical setting. Communication in such relationships may be geared toward team building, facilitating group process, collaboration, consultation, delegation, supervision, leadership, and management (see Chapter 10). You need a variety of communication skills, including presentational speaking, persuasion, group problem solving, providing performance reviews, and writing business reports.

Social and therapeutic interactions are needed between the nurse and members of the interprofessional team to build morale and strengthen relationships within the work setting. Within the interprofessional team, all members need friendship, support, guidance, and encouragement from one another to cope with the many stressors imposed by the demands of the health care context (Gottlieb & Feeley, 2006).

Nurse-Community Relationships

Many nurses form relationships with community groups by participating in local organizations, volunteering for community service, or becoming politically active. In a community-based practice, nurses establish relationships with their

community (Stanhope & Lancaster, 2012) (see Chapter 4). Communication in the nurse-community relationship includes neighbourhood newsletters, public bulletin boards, newspapers, radio, television, electronic information sites, and social media, whereby community health information is shared.

Elements of Professional Communication

Professional appearance, demeanour, and behaviour are important in establishing your trustworthiness and competence. They communicate the impression that you have assumed the professional helping role, are clinically skilled, and are focused on the patient. Professional behaviour should communicate warmth, friendliness, confidence, skill, and competence. Professionals speak in a clear, well-modulated voice, use good grammar, listen to other people, help and support colleagues, and communicate effectively. Being punctual, organized, well-prepared, and equipped for the responsibilities of the nursing role also communicate professionalism.

Courtesy

Common courtesy is part of professional communication. To practise courtesy, always greet and say goodbye to patients and knock on doors before entering. A courteous nurse will also state his or her purpose, address people by name, say "please" and "thank you" to members of the interprofessional team, and apologize for inadvertently causing distress. When a nurse is discourteous, he or she is perceived as rude or insensitive. Such behaviour sets up barriers between nurse and patient and causes friction among members of the interdisciplinary team.

Use of Names

Self-introduction is important. Failure to give a name, indicate status (e.g., student nurse, registered nurse, or licensed practical nurse), or acknowledge the patient creates uncertainty about the interaction and conveys a lack of commitment or caring. Making eye contact and smiling at other people communicates recognition. Addressing other people by name conveys respect for human dignity and uniqueness. Because using last names is respectful in most cultures, nurses usually use the patient's last name in the initial interaction, but they may use the first name in subsequent interactions at the patient's request. It is important to ask other people how they would like to be addressed and to honour their preferences. Using first names is appropriate for infants, young children, confused or unconscious patients, and close colleagues. Terms of endearment such as "honey," "dear," "Grandma," or "sweetheart" are inappropriate; they may be perceived as disrespectful and unprofessional. The use of plural pronouns such as "we" when referring to patients implies a loss of independence and may be interpreted as condescending. Referring to a patient by diagnosis, room number, or another attribute is demeaning and implies that you do not care enough to know the patient as an individual.

Trustworthiness

Trust entails relying on someone without doubt or question. Being trustworthy means following through on what you say you are going to do. To foster trust, you need to communicate warmth and demonstrate consistency, reliability, honesty, integrity, competence, and respect. Sometimes it is not easy for a patient to ask for help. Trusting another person involves

risk and vulnerability, but it also fosters open, therapeutic communication and enhances the expression of feelings, thoughts, and needs. Without trust, a nurse–patient relationship rarely progresses beyond social interaction and superficial care. Knowingly withholding key information, lying, or distorting the truth violates both legal and ethical standards of practice. Maintaining confidentiality and protecting a patient's privacy are also important aspects of communicating a trustworthy professional relationship. Sharing personal information or gossiping about other people communicates the message that you cannot be trusted and damages interpersonal relationships.

Autonomy and Responsibility

Autonomy is the ability to be self-directed and independent in accomplishing goals and advocating for other people. Nurses make choices and accept responsibility for the outcomes of their actions (Townsend, 2010). They take initiative in solving problems and communicate in a manner that reflects the importance and purpose of the therapeutic interaction (Arnold & Boggs, 2011). Recognizing the patient's autonomy is important to effective communication.

Assertiveness

Assertive communication allows individuals to act in their own best interests without infringing on or denying the rights of other people (Devito et al., 2011). Assertiveness conveys self-assurance and respect for other people (Austin & Boyd, 2010).

Nurses teach assertiveness skills to other people as a means of promoting personal health. Assertive people express feelings and emotions confidently, spontaneously, and honestly. They make decisions and control their lives more effectively than do nonassertive individuals. They can deal with criticism and manipulation by other people and learn to say no, set limits, and resist other people's efforts to impose guilt. For instance a nurse, when being asked to complete multiple tasks, may set limits by stating: "I will be able to get to that task, but only later today. Will that still work for you?"

Assertive responses are characterized by feelings of security, competence, power, optimism, and professionalism. They are good tools for dealing with criticism, change, negative conditions in personal or professional life, and conflict or stress in relationships. Assertive responses often contain "I" messages, such as "I want," "I need," "I think," and "I feel."

Communication Within the Nursing Process

In the following sections, the focus of the nursing process is on providing care for patients who need special assistance with communication. The section on implementation, to follow, contains examples of therapeutic communication techniques that are appropriate strategies for use in any interpersonal nursing situation.

❖ Assessment

Assessment of a patient's ability to communicate includes gathering data about the many contextual factors that influence communication. The word *context* refers to all the parts of a situation that help determine its meaning. A context

includes all the environmental factors that influence the nature of communication and interpersonal relationships. This includes the participants' internal factors and characteristics, the nature of their relationship, the situation prompting communication, the environment, and the sociocultural elements present (Beebe et al., 2011). Box 17-6 lists the contextual factors that influence communication. Understanding these contextual factors helps you make sound decisions during the communication process.

Physical and Emotional Factors

Assessing the psychophysiological factors that influence communication is especially important. Many altered health states and human responses limit communication. People with hearing or visual impairments have fewer channels through which to receive messages (see Chapter 47). Facial trauma, laryngeal cancer, tracheostomy, or endotracheal intubation

> BOX 17-6

Contextual Factors That Influence Communication

Psychophysiological Context

This refers to the internal factors that influence communication:

- Physiological status (e.g., pain, hunger, weakness, dyspnea)
- Emotional status (e.g., anxiety, anger, hopelessness, euphoria)
- Growth and development status (e.g., age, developmental tasks)
- Unmet needs (e.g., safety or security; love or belonging)
- Attitudes, values, and beliefs (e.g., meaning of illness experience)
- Perceptions and personality (e.g., optimistic or pessimistic, introverted or extroverted)
- Self-concept and self-esteem (e.g., positive or negative)

Relational Context

This refers to the nature of the relationship between the participants:

- Social, helping, or working relationship
- Level of trust between participants
- Level of caring expressed
- Level of self-disclosure between participants
- Shared history of participants
- Balance of power and control

Situational Context

This refers to the reason for the communication:

- Information exchange
- Goal achievement
- Problem resolution
- Expression of feelings

Environmental Context

This refers to the physical surroundings in which communication takes place:

- Privacy level
- Noise level
- Comfort and safety level
- Distraction level

Cultural Context

This refers to the sociocultural elements that affect the interaction:

- Educational level of participants
- Language and self-expression patterns
- Customs and expectations
- Media influences

often prevents movement of air past vocal cords or mobility of the tongue, which results in inability to articulate words. An extremely breathless person must use oxygen to breathe rather than speak. People with aphasia after a stroke or in late-stage Alzheimer's disease often cannot understand or form words. People with delirium cannot focus attentively, and those with dementia often cannot make sense of what is being said. Certain mental illnesses such as psychoses or depression cause patients to demonstrate flight of ideas (words do not keep up to rapidly changing thoughts), constant verbalization of the same words or phrases, a loose association of ideas, or slowed speech pattern. People who are highly anxious are sometimes unable to perceive environmental stimuli or hear explanations. Unresponsive or heavily sedated people cannot send or respond to verbal messages.

Review of the patient's medical record helps provide relevant information about the patient's ability to communicate. Through the health history and physical examination, you document physical barriers to speech, neurological deficits, and pathophysiological conditions that affect hearing or vision. Reviewing the patient's medication record is also important. For example, opiates, antidepressants, neuroleptics, hypnotics, or sedatives may cause a patient to slur words or use incomplete sentences. The nursing progress notes may reveal other factors that contribute to communication difficulties, such as the absence of family members who could provide more information about a confused patient.

Assessment should include communicating directly with patients to provide information about their ability to attend to, interpret, and respond to stimuli. If patients have difficulty communicating, it is important to assess the effects of the problem. Patients who cannot communicate effectively will often have difficulty expressing their needs and responding appropriately to the environment. A patient who is unable to speak is at risk for injury unless the nurse identifies an alternative communication method. Assistive communication tools and devices may support the nurse in assessment and communication more generally. Some of these tools involve assistive technologies, whereas others may be more simplistic, for example, nonverbal techniques such as simple sign language, lip reading, and so on (Finke et al., 2008). If barriers make it difficult to communicate directly with the patient, then family or friends become important sources of collateral information about the patient's communication patterns and abilities, as well as for general assessment.

Developmental Factors

Aspects of a patient's growth and development also influence nurse-patient communication. For example, an infant's self-expression is limited to crying, body movement, and facial expression, whereas most older children express their needs more directly, through speech and specific actions such as pointing. Nurses adapt communication techniques to the developmental needs of infants and children (see Chapters 21 and 22). Communication with children and their parents requires special considerations. It is important to include the parents, child, or both as sources of information about the child's health, depending on the child's age.

Advancing age may also affect communication abilities. According to Statistics Canada, older adults represent the fastest-growing sector of the population, of which 6 to 12% will experience speech, language, or voice difficulties (Canadian Association of Speech-Language Pathologists and Audiologists, 2011). Although some older adults have varied

► BOX 17-7 Focus on Older Adults

Tips for Improved Communication With Older Adults Who Have Communication Needs or Barriers

- Capture the patient's attention before speaking.
- Check for hearing aids and glasses.
- Introduce yourself.
- Choose a quiet, well-lit environment, and minimize visual and auditory distractions.
- Face the patient, and use facial expressions and gestures as needed.
- Amplify your voice if necessary, but do not shout because it distorts sound and your facial expression could be misinterpreted. Speak clearly at a moderate rate.
- Allow time for the patient to respond. Do not assume the patient is being uncooperative if the patient makes no response or a delayed response.
- Give patients time to ask questions and clarify responses.
- Whenever possible, ask a family member or caregiver to join you and the patient in the room. Such people are usually most familiar with the patient's communication patterns and can assist in the communication process.

communication barriers, nurses need to avoid the patronizing tone of what is referred to as “**elderspeak**,” or condescending baby talk. Rather, nurses should communicate simply, clearly, and with respect to provide humanistic care for the unique needs of their older patients (Cunningham & Williams, 2007). Box 17-7 highlights tips for communicating with older adults who have communication needs and barriers. These tips can be applied to all patients with communication problems.

Sociocultural Factors

Culture, like communication more broadly, is a process that is experienced between people in a relationship. Awareness of the relational process of culture, beginning with an appreciation of one's own individual perspective, power, and privilege, can facilitate communication and understanding between nurses and their patients (see Chapter 9). Nurses can communicate in what is considered “culturally safe” **relational practice** (Hartrick Doane & Varcoe, 2005) by responding to their patients and families, following their lead, appreciating their unique contexts, acknowledging difference, and engaging with the relational capacities mentioned earlier.

Make a conscious effort to avoid interpreting messages from your own cultural perspective and to consider communication within the context of the patient's background.

Gender

Gender is another factor that influences how people think, act, feel, and communicate. Male and female communication patterns tend to differ, which can sometimes create barriers to effective communication (Beebe et al., 2011). Males tend to use less verbal communication but are more likely to initiate conversations and address issues directly. Females tend to disclose more personal information, use more active listening, and respond in ways that encourage continued conversation. A male nurse might say to his colleague, “Help me turn Jeremy.” A female nurse might say, “Jeremy needs to be turned,” expecting her colleague to understand the implied request for help.

To practise gender sensitivity in communication, recognize the differences in male and female communication patterns to

avoid misinterpreting messages sent by someone of the opposite gender. Conversations with sexual overtones, gender-denigrating jokes, and male–female stereotyping communicate a lack of professionalism.

❖Nursing Diagnosis

Most individuals experience difficulty with some aspect of communication. People who are free of illness or disability may lack skills in attending, listening, responding, and self-expression. Often, nurses will direct care toward individuals who experience more serious communication impairments, though support for everyone's communication regardless of abilities is part of the nursing process.

The primary nursing diagnostic label used to describe the patient with limited or no ability to communicate verbally is *impaired verbal communication*. This is the state in which the ability to receive, process, transmit, and use symbols is decreased or absent (Doenges et al., 2010). Defining characteristics include the inability to articulate words, inappropriate verbalization, difficulty forming words, and difficulty in comprehending, which the nurse clusters together to form the diagnosis. This diagnosis is useful for a wide variety of patients with special problems and needs related to communication, such as impaired perception, reception, and articulation. Although a patient's primary problem may be impaired verbal communication, the associated difficulty in self-expression or altered communication patterns may also contribute to other nursing diagnoses:

- Anxiety
- Social isolation
- Ineffective coping
- Compromised family coping
- Powerlessness
- Impaired social interaction

Contributing and contextual factors for a nursing diagnosis focus on the origins of the communication disorder. In the case of impaired verbal communication, these are physiological, mechanical, anatomical, psychological, social/cultural, or developmental in nature. Accuracy in the identification of related factors is necessary in order to select interventions that can effectively resolve the problem. For example, the diagnosis of *impaired verbal communication related to cultural diversity* would be managed very differently than the diagnosis of *impaired verbal communication related to deafness*.

❖Planning

Once you have identified the origins and context of the patient's communication impairment, you must consider several factors as you design a responsive approach and nursing care plan. Motivation is a factor in improving communication; patients often must be encouraged to try different approaches. It is especially important to involve the patient and family in decisions about the plan of nursing care to determine whether suggested methods are acceptable. Patients and families must be patient with themselves and each other when learning new skills if communication is to be effective. When the focus is on practising communication, in some instances arranging for a quiet, private place, free of distractions may be helpful. Communication aids, such as a writing board for a patient with a tracheostomy, an electronic communication device for a patient with autism, or a special call system for a patient with paralysis, may enhance communication.

Goals and Outcomes

The primary goal of nursing interventions is to facilitate the development of trust between the patient and members of the health care team. It is important to identify expected outcomes for all patients, particularly when impaired communication is a concern. Outcomes are specific and measurable and provide the means to determine whether the broader goal is met. For example, outcomes for the patient might be as follows:

- The patient initiates conversation about diagnosis or health care problem.
- The patient is able to attend to appropriate stimuli.
- The patient conveys clear and understandable messages with family members and members of the health care team.
- The patient expresses increased satisfaction with the communication process.

At times, you will care for well patients whose difficulty in sending, receiving, and interpreting messages interferes with healthy interpersonal relationships. In this case, impaired communication may be contributing to other nursing diagnoses such as *impaired social interaction* or *ineffective coping*. In such cases, you need to plan interventions to help your patients improve their communication skills. For example, you could model effective communication techniques and provide feedback regarding the patient's communication. Role playing helps patients rehearse situations in which they have difficulty communicating. Expected outcomes for a patient in this situation might include demonstrating the ability to appropriately express needs, feelings, and concerns; communicating thoughts and feelings more clearly; engaging in appropriate social conversation with peers and staff; and increasing feelings of autonomy and assertiveness.

Setting of Priorities

It is essential for the nurse to be available for communication with some immediacy so that the patient is able to express any pressing needs or problems. This may involve an intervention as simple as keeping a call light within reach for a patient restricted to bed or providing a communication augmentative device for the patient to use (e.g., message board, Braille keyboard). When you plan to have lengthy interactions with a patient, it is important to address physical care priorities (i.e., pain or elimination needs) first, so that the patient is comfortable and the discussion is uninterrupted.

Continuity of Care

To ensure an effective care plan, you may need to collaborate with other members of the interprofessional team who have expertise in communication strategies. Speech therapists help patients with aphasia, interpreters may be of use to communicate with patients who speak a diversity of languages, and psychiatric nurse specialists support communication with patients in crisis, those who may be experiencing altered moods, behaviours, anxiety states, or disordered thoughts and perceptions (Austin & Boyd, 2010).

❖Implementation

In carrying out any care plan, nurses use communication techniques that are appropriate for the patient's individual needs. Before learning how to adapt communication methods to help patients with serious communication impairments, it is necessary to learn the communication skills and approaches that serve as the foundation for professional communication. It is

also important to understand approaches that create barriers to effective interaction (Devito et al., 2011).

Therapeutic Communication Techniques

Therapeutic communication techniques are specific responses that encourage the expression of feelings and ideas and convey acceptance and respect. By learning these techniques, you develop awareness of the variety of nursing responses available for use in different situations. Although some of the techniques seem artificial at first, skill and comfort in using them increase with practice. Tremendous satisfaction will result from the development of therapeutic relationships and achievement of desired patient outcomes.

Active Listening. Active listening means to be attentive to what the patient is saying both verbally and nonverbally. It enhances trust and facilitates patient communication because it demonstrates acceptance and respect for the patient. Several nonverbal skills facilitate active listening. They can be identified by the acronym *SOLER* (Townsend, 2010):

- S:** *Sit* facing the patient. This posture indicates that you are there to listen and are interested in what the patient is saying.
- O:** Keep an *open* posture (i.e., keep arms and legs uncrossed). This posture suggests that you are receptive (“open”) to what the patient has to say. A “closed” position may convey a defensive attitude, possibly invoking a similar response in the patient.
- L:** *Lean* toward the patient. This posture indicates that you are involved and interested in the interaction.
- E:** Establish and maintain intermittent *eye contact*. This behaviour conveys your involvement in and willingness to listen to what the patient is saying. Absence of eye contact or shifting of the eyes indicates that you are not interested in what the patient is saying.
- R:** *Relax*. It is important to communicate a sense of being relaxed and comfortable with the patient. Restlessness communicates a lack of interest and also conveys a sense of discomfort that may extend to the patient.

Sharing Observations. Nurses make observations by commenting on how the patient looks, sounds, or acts. Stating observations often helps the patient communicate without the need for extensive questioning, focusing, or clarification. This technique helps start a conversation with quiet or withdrawn people. Do not state observations that might anger, embarrass, or upset the patient, such as telling someone “You look a mess!” Even if such an observation is made with humour, the patient may be offended or feel belittled.

Sharing observations differs from making assumptions, which means drawing unwarranted conclusions about the patient without validating them. Making assumptions puts the patient in the position of having to contradict the nurse. Examples might include the nurse interpreting fatigue as depression or assuming that untouched food indicates lack of interest in meeting nutritional goals. Making observations is a gentler approach of simply witnessing without judgement about what might be happening: “You look tired” is very different from the attached judgement of “You look tired. Were you up all night?”; “You seem different today” is different from “You seem much better today” and simply stating “I see you are wearing lipstick today” conveys something quite distinct from “You look very beautiful.”

Sharing Empathy. Empathy is the ability to emotionally and intellectually understand another person’s reality, to

accurately perceive unspoken feelings, and to communicate this understanding to the other person (Devito et al., 2011). Empathy is expressed when you seek to explore the perspective of another person. Cultivating an ability to empathize requires patience, a sense of curiosity, and a willingness to understand a patient’s context and viewpoint. This requires a relational approach starting with a willingness to open the relational space and take action. Empathy can also be expressed in relational communication through strong **intentionality**, or a consciousness of the purpose and intention of one’s communication, and reflexivity, which is an attention to one’s responses and feelings as they influence communication and decision making (Hartick Doane & Varcoe, 2007). Such empathic understanding requires you to be self-aware, sensitive, and imaginative, especially if you have not had similar experiences. Statements reflecting empathy are highly effective because they indicate you heard the emotional content, as well as the factual content, of the communication. Empathic statements are neutral and nonjudgemental and help to provide validation to the patient and establish a trusting relationship. For example, to an angry patient who has limited mobility after a stroke, you might say, “It must be very frustrating to know what you want to do and not be able to do it.”

Sharing Hope. You must recognize that hope is essential for healing, and you must learn to communicate a “sense of possibility” to other people. Appropriate encouragement and positive feedback are important in fostering hope and self-confidence and for helping people achieve their potential and reach their goals. You can instill hope by commenting on the positive aspects of the other person’s behaviour, performance, or response. Sharing a vision of the future is a way of reimagining their situation, which can foster hopefulness and creativity through communication. Reminding patients of their internal resources and coping abilities also conveys a sense of hope and strengthens relational communication. You can reassure patients that many kinds of hope exist, and that meaning and personal growth can arise from illness experiences. For example, you might say to a patient discouraged about progressive changes in mobility: “I have seen your courage and creativity in the past and am curious about how you might be preparing for the changes in your abilities now.”

Sharing Humour. Humour is an important but under-used resource in nursing communication (Wilkins & Eisenbraun, 2009). Research suggests that a sense of humour is a useful coping strategy for patients, health care providers, and families and an essential communication tool for nurses as it can strengthen the helping relationship (Wanzer et al., 2005). Humour has been shown to have positive effects on both a person’s emotional and physiological state (Tse et al., 2010; Wilkins & Eisenbraun, 2009).

Humour is not without potential communication challenges. It is common for nurses to care for patients from diverse cultures. When nurses interact with patients who communicate in languages other than their own, it is important to acknowledge that nuances of jokes and humour can be misunderstood. Similarly, when either a nurse or a patient attempts to communicate humour while speaking in a language other than their most familiar, mistakes and misunderstandings may also occur. Regardless of culture or background, what is humorous to one person simply may not be funny to another.

Health care providers sometimes use negative humour as a way to deal with extreme tension and stress in the workplace,

but it can be problematic. What is referred to as “grey zone” humour constitutes behaviours like teasing, practical jokes, and sarcasm. “Gallows humour” speaks to the more grim or dark style, often used in very difficult situations to relieve anxiety or release anger to transform negative feelings into something lighter in mood. This humour frequently includes topics such as body fluids, body parts, physical or slapstick humour, and so on (Buxman, 2008). This style of humour has a high potential to be perceived as tasteless and lacking in caring by people uninvolved in the situation. When nurses use this style of humour within earshot of patients or their loved ones, great emotional distress can result. When used judiciously and carefully, a nurse’s use of humour in communication with patients can be a highly therapeutic strategy.

Sharing Feelings. Emotions are subjective feelings that result from thoughts and perceptions. Feelings are not right, wrong, good, or bad, although they may be experienced as pleasant or unpleasant. Even though withholding feelings can increase stress and exacerbate illness, people may do so in an attempt to ward off unpleasant feelings or adhere to expectations of others or societal norms. You can gently help patients express their emotions by making observations, acknowledging feelings, encouraging communication, giving them permission to express “negative” feelings, and modelling healthy emotional self-expression. At times, patients direct anger or frustration prompted by their illness toward nurses, who should not take such expressions personally. Acknowledging patients’ feelings demonstrates empathy and communicates that you have listened to and understood the emotional aspects of their situation.

When you care for patients, you must be aware of your own emotions because strong feelings may be difficult to hide. Students may wonder whether it is helpful for nurses to share their feelings with patients. Sharing emotion makes nurses seem more human and often brings people closer. It is appropriate to share feelings of caring, or even cry with other people, as long as you are in control of the expression of those feelings and do so in a way that does not burden the patient or break confidentiality. Patients are perceptive and can sense a nurse’s emotions. It is usually inappropriate, and may interfere with assessing and caring for the patient, to discuss one’s negative personal emotions such as anger or sadness with patients. A social support system of colleagues is helpful, as are strategies for supervision and debriefing; employee assistance programs, peer group meetings, and the use of interprofessional teams such as social work and pastoral care may provide avenues for nurses to safely express feelings away from patients.

Using Touch. Many patients experience feelings of isolation related to their personal and social contexts, as well as the increasing technological features of society more generally. Thus, nurses are required, more than ever, to communicate a human connection to their patients (see Chapter 18). Touch is an important element of communication that conveys many messages, such as affection, emotional support, encouragement, tenderness, and personal attention. People have unique perspectives on touch based upon their past experiences and health conditions. For instance, patients in psychosis may misinterpret touch as threatening; patients who have experienced abusive or violent contact from others may be fearful of even well-intentioned touch from a nurse. Touch may also be misinterpreted as sexual or romantic by some patients (Gleeson & Higgins, 2009). In response to the patient’s lead, holding a hand or offering a gentle touch on the shoulder may, however,

Figure 17-2 The nurse uses touch to communicate.

be an expression of comfort, reassurance, and care for some, and may convey empathy in situations when words are insufficient (Arnold & Boggs, 2011) (Figure 17-2).

Students may initially find giving intimate care stressful, especially when caring for patients of the opposite gender. Students learn to cope with intimate contact by changing their perception of the situation. Because much of what nurses do involves touch, you must learn to be sensitive to people’s reactions to touch and communicate effectively when touch is required. Touch should be as gentle or as firm as needed and delivered in a comforting, nonthreatening manner. In certain situations, you must withhold touch, for example, when interacting with highly suspicious or angry people who may respond negatively or even violently when touched.

Using Silence. It takes time and experience to become comfortable with silence. Most people have a natural tendency to fill silences with words, but sometimes silences serve the need for time for the nurse and patient to observe one another, to really *listen*, to sort out their feelings, think about how to say things, and consider what has been communicated. Silence is an important skill in the capacity to *let be* and to live with *complexity and ambiguity* (Hartrick Doane & Varcoe, 2005). Silence may provide sufficient space for some patients to talk freely without the constraint of relying upon particular patterns of question and answer. Silence allows patients to think and gain insight into their situations crucial to *reimagining* and hope. In general, you should allow the patient to initiate when the silence is to be broken (Austin & Boyd, 2010).

Silence is particularly useful when people are confronted with decisions that require much thought. For example, silence may help a patient gain confidence needed to share the decision to refuse medical treatment. Silence also allows the nurse to attend to nonverbal messages such as worried expressions or loss of eye contact. Remaining silent demonstrates the nurse’s patience and responsiveness to the patient who may be unable to reply quickly. Silence may be especially therapeutic during times of profound sadness or grief (Box 17-8).

Providing Information. Providing relevant information that the patient needs or wants to know empowers the patient to make informed decisions, experience less anxiety, and feel safe and secure. It is also an integral aspect of health teaching. Hiding information from patients is not usually helpful, particularly when they are seeking it. If a physician withholds information, you need to clarify the reason with the physician.

BOX 17-8 NURSING STORY

Communication With a Dying Patient

A young third-year nursing student who was assigned to care for a dying patient came to me, as her nursing instructor, to discuss her assignment. The student nurse appeared to be anxious and distraught and was tearful. She requested a change of assignment and, when asked why she felt she needed to be moved, she stated: "I just don't know what I'm supposed to be *doing* with her. She is asking for her family, but they aren't there. She's dying and I just don't know what to do to *help* her." I asked the student what she was doing while she was in the room and she said: "I'm just sitting there holding her hand and listening to her when she's awake. She really isn't talking much, and she drifts off to sleep a lot, but she's afraid of being left alone, so I'm just holding her hand and letting her know I'm there, even when she's sleeping; that way she'll know she's not alone whenever she wakes up. I make sure she's comfortable but I don't know what else she needs. I'm just not *doing* anything." As I looked into her tear-filled eyes, I simply asked her, "So, what makes you think you aren't doing anything?" Communication involves so much more than dialogue. In this case, communication involved very little verbal interaction; it involved active listening, shared empathy, comfort care, gentle touch, silence, presence, and "being with," as the student compassionately accompanied the patient through her final stage of life and assisted with her transition into death.

Patients have a right to know about their health status and what is happening in their environment. Information of a distressing nature needs to be communicated with sensitivity, at a pace appropriate to what the patient can absorb, and in general terms at first: "John, your heart sounds have changed from earlier today, and so has your blood pressure. I'll let your doctor know." It is important to provide information that enables patients to understand what is happening and what to expect: "Ms. Evans, John is getting an echocardiogram right now. This test uses painless sound waves to create a moving picture of his heart structures and valves and should tell us what is causing his murmur."

Clarifying. To check whether understanding is accurate, restate an unclear or ambiguous message to clarify the sender's meaning or ask the other person to rephrase it, explain further, or give an example of what he or she means. Without clarification, you may make invalid assumptions and miss valuable information. Despite efforts at paraphrasing, you sometimes will still not understand the patient's message and should let the patient know that this is the case: "I'm not sure I understand what you mean by 'sicker than usual.' What is different now?"

Focusing. Focusing centres on key elements or concepts of a message. If conversation is vague or rambling or if patients begin to repeat themselves, focusing is a useful technique. Do not use focusing if it interrupts patients while they are discussing an important issue. Rather, use focusing to guide the direction of conversation to important areas: "We've talked a lot about your medications, but let's look more closely at the trouble you're having in taking them on time."

Paraphrasing. Paraphrasing is restating another person's message more briefly in your own words. Through paraphrasing, you let the patient know you are actively involved in the search for understanding. Practice is required to paraphrase accurately. If the meaning of a message is changed or distorted through paraphrasing, communication becomes

ineffective. For example, a patient may say, "I've been overweight all my life and never had any problems. I can't understand why I need to be on a diet." Paraphrasing this statement by saying, "You don't care if you're overweight or not," is incorrect. It would be more accurate to say, "I hear you saying that you're not convinced you need a diet because you've stayed healthy."

Asking Relevant Questions. Nurses ask relevant questions to seek information needed for decision making. You should ask only one question at a time and fully explore one topic before moving to another area. During patient assessment, questions should follow a logical sequence and proceed from general to more specific. Open-ended questions allow the patient to take the conversational lead and introduce pertinent information about a topic. For example, "What's your biggest concern at the moment?" Focused questions are used when more specific information is needed in an area: "How has your pain affected your life at home?" Allow patients to fully respond to an open-ended question before asking more focused questions. Closed-ended questions elicit yes, no, or one-word responses: "How many times a day are you taking pain medication?" Although they are helpful during assessment, they are generally less useful during therapeutic exchanges.

Asking too many questions is sometimes dehumanizing. Seeking primarily factual information does not allow you or your patient to establish a meaningful relationship or deal with important emotional issues. It is a way to ignore uncomfortable areas in favour of more comfortable, neutral topics. A useful exercise is to try conversing without asking the other person a single question. By giving general leads ("Tell me about it"), making observations, paraphrasing, focusing, providing information, and so forth, you may discover important information that would have remained hidden if communication were limited primarily to questions.

Summarizing. Summarizing is a concise review of key aspects of an interaction. Summarizing brings a sense of satisfaction and closure to an individual conversation and is especially helpful during the termination phase of a nurse-patient relationship. By reviewing a conversation, participants focus on key issues and add relevant information as needed. Beginning a new interaction by summarizing a previous one helps the patient recall topics discussed and shows the patient that you have analyzed the communication. Summarizing also clarifies expectations, as in this example of a nurse manager who has been working with a dissatisfied employee: "You've told me a lot of reasons about why you don't like this job and how unhappy you've been. We've also come up with some possible ways to make the situation better, and you've agreed to try some and let me know if any of them help."

Self-Disclosure. Self-disclosures are subjectively true, personal experiences about the self that are intentionally revealed to another person. This is not therapy for the nurse; rather, it shows patients that you understand and that their experiences are not unique. You may choose to share experiences or feelings that are similar to those of the patient and emphasize both the similarities and differences. This kind of self-disclosure is indicative of the closeness of the nurse-patient relationship and involves a particular kind of respect for the patient. It is offered as an expression of genuineness and honesty and is an aspect of empathy (Austin & Boyd, 2010). Self-disclosure should be relevant and appropriate and made to benefit the patient. Self-disclosure should be used sparingly so that the patient remains the focus of the interaction: "That happened to me once, too. I was devastated . . . I went for

counselling, and it really helped. What are your thoughts about seeing a counsellor?"

Confrontation. To confront someone in a therapeutic way, you help the other person become more aware of inconsistencies in his or her feelings, attitudes, beliefs, and behaviours (Austin & Boyd, 2010). This technique improves patient self-awareness and helps the patient recognize growth and deal with important issues. Confrontation should be used only after you have established a trusting relationship with the patient, and it requires gentleness and sensitivity: "You say you've already decided what to do, but you're still talking a lot about your options."

Nontherapeutic Communication Techniques

Certain communication techniques hinder or damage professional relationships. These specific techniques are referred to as *nontherapeutic* or *blocking* and will often cause recipients to activate defences to avoid being hurt or negatively affected. Nontherapeutic techniques tend to discourage further expression of feelings and ideas and may engender negative responses or behaviours in other people.

Asking Personal Questions. Asking personal questions that are not relevant to the situation but simply to satisfy your curiosity (e.g., "Why don't you and John get married?") is not appropriate professional communication. Such questions are invasive and unnecessary. If patients wish to share private information, they will. To learn more about the patient's interpersonal roles and relationships, ask a question such as "How would you describe your relationship with John?"

Giving Personal Opinions. When you provide a personal opinion (e.g., "If I were you, I'd put your mother in a long-term care facility"), it takes decision making away from the patient. It inhibits spontaneity, stalls problem solving, and creates doubt. Personal opinions differ from professional advice. At times, patients need suggestions and help to make choices. Suggestions should be presented to patients as options because the final decision rests with the patient. Remember that the problem and its solution belong to the patient. A much better response is "Let's talk about what options are available for your mother's care."

Changing the Subject. When another person is trying to communicate something important, changing the subject (e.g., "Let's not talk about your problems with your job. It's time for your walk") is rude and shows a lack of empathy and mutuality. It tends to block further communication, and the sender then withholds important messages or fails to openly express feelings. Thoughts and spontaneity are interrupted, ideas become tangled, and information provided may be inadequate. In some instances, changing the subject serves as a face-saving manoeuvre. If this happens, reassure the patient that you will return to his or her concerns: "After your walk, let's talk some more about what's going on with your job."

Automatic Responses. Stereotypes (e.g., "Older adults are always confused" or "Administration doesn't care about the staff") and labels are generalized beliefs held about people. A cliché is a generalizing comment such as "You can't win them all" that tends to belittle the other person's feelings and minimize the importance of his or her message. These automatic responses communicate that you are not taking concerns seriously or responding thoughtfully. Another kind of automatic response is parroting, repeating what the other person has said, word for word. Parroting is easily overused and is not as effective as paraphrasing. Automatic remarks about

other people lead to assumptions and closed communication that reflects poor nursing judgement and may well threaten nurse-patient or nurse-team relationships. Nurses may get in the habit of these automatic responses as a defence mechanism or as a way to compartmentalize and organize their work.

A nurse who is excessively task-oriented automatically makes the task or procedure the entire focus of interaction with patients, missing opportunities to communicate with patients as individuals and meet their needs. When you first perform technical tasks, you may have difficulty integrating therapeutic communication because of your need to focus on the procedure. In time, you will learn to integrate communication with high-visibility tasks and accomplish several goals—including relational communication—simultaneously. Self-awareness is crucial (Austin & Boyd, 2010).

False Reassurance. When a patient is seriously ill or distressed, you may be tempted to offer hope to the patient with statements such as "Don't worry, everything will be all right"; "You'll be fine"; or "You have nothing to worry about." When a patient is reaching for understanding, false reassurance discourages open communication. Offering reassurance not supported by facts or based in reality does more harm than good. Although you may be attempting to be kind, such reassurance has the secondary effect of helping you avoid the patient's distress, tends to block conversation, and discourages further expression of feelings. A more facilitative nursing response is "It must be difficult not to know what the surgeon will find. What might be helpful to you at this time?"

Sympathy. Sympathy is concern, sorrow, sadness, or pity felt for the patient generated by personal identification with the patient's needs (Grover, 2005). Sympathy is a subjective vision of another person's viewpoint that prevents a clear perspective of the issues confronting that person. If you over-identify with the patient (e.g., "I'm so sorry about your mastectomy; it must be terrible to lose a breast"), you will lose objectivity and be unable to effectively help the patient work through his or her situation (Arnold & Boggs, 2011). Although sympathy is a compassionate response to another's situation, it may not be as responsive and therapeutic as empathy. A more empathic approach is "The loss of a breast is a major change. How do you think it will affect your life?"

Asking for Explanations. You may be tempted to ask your patient to explain why he or she believes, feels, or has acted in a certain way (e.g., "Why are you so anxious?"). Patients frequently interpret "why" questions as accusations or think you already know the reason and are simply testing them. "Why" questions tend to interrupt patients' descriptions of their feelings and experience and cause them to refocus their energy into intellectual or defensive responses (Shattell & Hogan, 2005). Regardless of your motivation, "why" questions can cause resentment, insecurity, and mistrust. If you require additional information, it is best to phrase questions to avoid using "why": "You seem upset. What's on your mind?" or "Tell me about how you are feeling today compared to yesterday" is more likely to help the anxious patient to communicate.

Approval or Disapproval. Do not impose your personal attitudes, values, beliefs, and moral standards on other people while in the professional helping role (e.g., "You shouldn't even think about assisted suicide; it's not right"). Other people have the right to speak their minds and make their own decisions. Judgemental responses often contain terms such as *should*, *ought*, *good*, *bad*, *right*, and *wrong*. Agreeing or disagreeing conveys the subtle message that you are making value

judgements about the patient's decisions. Approving implies that the behaviour being praised is the only acceptable one. Often the patient shares a decision not in an effort to seek approval but to provide a means to discuss feelings. On the other hand, disapproving implies that the patient needs to meet your expectations or standards. Instead, help patients explore their own beliefs and decisions. The nursing response "I'm surprised you're considering assisted suicide; tell me more" gives the patient a chance to express ideas or feelings without fear of being judged.

Defensive Responses. Becoming defensive in response to criticism (e.g., "No one here would intentionally lie to you") implies that the other person has no right to an opinion. The sender's concerns are ignored when you focus on the need for self-defence, defence of the health care team, or defence of other people. When patients express criticism, it is important to listen to what they have to say. Listening does not imply agreement. To discover reasons for the patient's anger or dissatisfaction, you must listen without defensiveness or judgement and criticism. By avoiding defensiveness, you can defuse anger and uncover deeper concerns: "It sounds as if you believe people have been dishonest with you. That must make it difficult for you to trust anyone."

Passive or Aggressive Responses. Passive responses (e.g., "Things are bad, and I can't do anything about it") serve to avoid conflict or sidestep issues. They reflect feelings of sadness, depression, anxiety, powerlessness, and hopelessness. Aggressive responses (e.g., "Things are bad, and it's all your fault") provoke confrontation at the other person's expense and reflect feelings of anger, frustration, resentment, and stress. When nurses lack assertiveness skills, they may also use triangulation, complaining to a third party rather than confronting the problem or expressing concerns directly to the source. This lowers team morale and draws other people into the conflict situation. Assertive communication establishes boundaries and expectations without the blame or judgement implied in passive and aggressive responses. An assertive approach imparts intention and action that will support the ongoing professional therapeutic relationship.

Arguing. Challenging or arguing against perceptions (e.g., "How can you say you didn't sleep a wink, when I heard you snoring all night long?") denies that they are real and valid to the other person. They imply that the other person is lying, misinformed, or uneducated. Skillful nurses give information or present reality in a way that avoids argument: "You feel as if you didn't get any rest at all last night, even though I thought you slept well because you seemed peaceful when I checked your room during the night."

Adapting Communication Techniques for the Patient With Special Needs

The temporary or permanent loss of the ability to speak is extremely traumatic to an individual. It is important to assess a patient's alternative communication method and whether it causes anxiety in the patient. Patients who have undergone laryngectomies often write notes, use communication boards or laptop computers, speak with mechanical vibrators, or use esophageal speech. Patients with endotracheal or tracheostomy tubes have a temporary loss of speech. Most use a notepad to write their questions and requests. However, the patient may become incapacitated and unable to write messages. You need to determine whether the patient has developed a sign language or system of symbols to communicate

needs. If not, you may need to assist the patient in developing a meaningful method during a new or temporary loss of communication.

Interacting effectively with patients who have conditions that impair communication requires special thought, sensitivity, creativity, and responsiveness. Such patients benefit greatly when you adapt communication techniques to their unique circumstances or developmental level. For example, if you are caring for a patient with impaired verbal communication related to mechanical ventilation, you can provide a visual table or construct a coded hand signal to exchange necessary communication. You and the patient can use such tools to help communicate for assessment and interventions. Similar techniques can be used with patients suffering with aphasia or some dementias.

Patients with **aphasia** may be unable to produce or understand language. **Expressive aphasia**, a motor type of aphasia, is the inability to name common objects or to express simple ideas in words or writing. For example, a patient may understand a question but be unable to express an answer. **Sensory or receptive aphasia** is the inability to understand written or spoken language. The patient may be able to express words but is unable to understand the questions or comments of others. **Global aphasia** is the inability to understand language or communicate orally.

You need to direct nursing actions toward meeting the goals and expected outcomes identified in the plan of care, addressing both the communication impairment and its contributing factors. Box 17-9 lists many methods available to encourage, enhance, restore, or substitute for verbal communication. You must be sure that the patient is physically able to use the chosen method and that it does not cause frustration by being too complicated or difficult.

Effective communication involves adapting to any special needs resulting from sensory, motor, or cognitive impairments that are present.

◆Evaluation

To determine whether the plan of care has been successful, both nurse and the patient evaluate the patient's communication outcomes. You need to evaluate nursing interventions to determine what strategies or interventions were effective and what changes in the patient's situation resulted because of the interventions. For example, if using pen and paper proves frustrating for a nonverbal patient whose handwriting is shaky, you need to revise the care plan to include use of a picture board instead. If expected outcomes are not met or progress is not satisfactory, you need to determine what factors influenced the outcomes and then modify the plan.

You can evaluate the effectiveness of your own communication by videotaping practice sessions with peers, making recordings, and analyzing written records of your verbal and nonverbal interactions with patients. Process recording analysis reveals faults in personal communication techniques, so that you can improve their effectiveness. Box 17-10 contains a sample communication analysis of such a record. Analyzing a process recording enables you to evaluate the following:

- Determine whether the nurse encouraged openness and allowed the patient to "tell his or her story," expressing both thoughts and feelings.
- Identify any missed verbal or nonverbal cues or conversational themes.

► BOX 17-9 Communicating With Patients Who Have Special Needs

Patients Who Cannot Speak Clearly (Aphasia, Dysarthria, Muteness)

- Listen attentively, be patient, and do not interrupt.
- Ask simple questions that require yes or no answers.
- Allow time for understanding and response.
- Use visual cues (e.g., words, pictures, and objects) when possible.
- Allow only one person to speak at a time.
- Do not shout or speak too loudly.
- Encourage the patient to converse.
- If you have not understood the patient, let him or her know.
- Collaborate with a speech therapist as needed.
- Use communication aids:
 - Pad and felt-tipped pen or Magic Slate
 - Communication board with commonly used words, letters, or pictures denoting basic needs
 - Call bells or alarms
 - Sign language
 - Use of eye blinks or movement of fingers for simple responses ("yes" or "no")

Patients Who Are Cognitively Impaired

- Reduce environmental distractions while conversing.
- Capture patient's attention before you speak.
- Use simple sentences, and avoid long explanations.
- Ask one question at a time.
- Allow time for the patient to respond.
- Be an attentive listener.
- Include family and friends in conversations, especially in topics known to the patient.

Patients Who Are Hearing Impaired

- Check for the presence of hearing aids and glasses.
- Reduce environmental noise.
- Get the patient's attention before you speak.
- Face the patient so that your mouth is visible.
- Do not chew gum.
- Speak at normal volume; do not shout.

- Rephrase rather than repeat, if your message is misunderstood.
- Provide a sign language interpreter if this is indicated.

Patients Who Are Visually Impaired

- Check for use of glasses or contact lenses.
- Identify yourself when you enter room, and notify patient when you leave room.
- Speak in a normal tone of voice.
- Do not rely on gestures or nonverbal communication to convey messages.
- Use indirect lighting, avoiding glare.
- Use an appropriate font size for the impairment (i.e., at least 14-point print).

Patients Who Are Unresponsive

- Call the patient by name during interactions.
- Communicate both verbally and by touch.
- Speak to the patient as though he or she can hear.
- Explain all procedures and expected sensations.
- Provide orientation to person, place, and time.
- Avoid talking about patient to other people in his or her presence.
- Avoid saying things that the patient should not hear (e.g., gossip or speculations about patient's condition).
- Always assume that patients can hear and understand everything said at their bedside.

Patients Who Do Not Speak English

- Speak to the patient in a normal tone of voice (shouting may be interpreted as anger).
- Establish a method for the patient to signal a desire to communicate (call light or bell).
- Provide an interpreter (translator) as needed.
- Develop communication board, pictures, or cards.
- Translate words from the English list into the patient's native language for the patient to make basic requests.
- Ensure that a dictionary (English-French, English-Blackfoot, and so forth) is available if patient can read.

- Examine whether nursing responses blocked or facilitated the patient's efforts to communicate.
- Determine whether nursing responses were positive and supportive or superficial and judgmental.
- Examine the type and number of questions that were asked.
- Determine the type and number of therapeutic communication techniques used.
- Discover any missed opportunities to use humour, silence, or touch.
- Evaluation of the communication process helps you gain confidence and competence in interpersonal skills. Becoming an effective communicator greatly increases your professional satisfaction and success. No skill is more basic, and no tool more powerful, than communication.

✦ KEY CONCEPTS

- Communication is a powerful therapeutic tool and an essential nursing skill used to influence other people and achieve positive health care outcomes.
- Relational practice depends upon approaches to communication that enhance the nurse's capacity to be in relation to patients in often very uncertain and difficult circumstances.

- Communication involves the entire human being: body, mind, emotions, and spirit.
- Critical thinking facilitates communication through creative inquiry, focused self-awareness, reflexivity, empathy, and awareness of other people, as well as the intentionality of purposeful analysis, and control of perceptual biases.
- Nurses consider many contexts and factors influencing communication when making decisions about what, when, where, how, why, and with whom to communicate.
- Nurses use intrapersonal, interpersonal, transpersonal, small-group, and public interaction to achieve positive change and health goals.
- Communication is most effective when the receiver and sender accurately perceive the meaning of each other's messages.
- Message transmission is influenced by the sender's and receiver's physical and developmental status, perceptions, values, emotions, knowledge, sociocultural background, roles, and environment.
- Effective verbal communication requires appropriate vocabulary, intonation, clear and concise phrasing, proper pacing of statements, and proper timing and relevance of a message.

► BOX 17-10 Sample Communication Analysis

NURSE: Good morning, Mr. Simpson. [Smiles and approaches bed, holding clipboard]

- Acknowledging by name, social greeting to begin conversation

PATIENT: What's good about it? [Arms crossed over chest, frowning, with a direct stare]

- Nonverbal signs of anger

NURSE: You sound unhappy. [Pulls up chair and sits at bedside]

- Sharing observation, nonverbal communication of availability

PATIENT: You'd be unhappy, too, if nobody would answer your questions. [Angry tone of voice, challenging expression]

- Further expression of feelings, facilitated by nurse's accurate observation

NURSE: This hospital has a fine staff, Mr. Simpson. I'm sure no one would intentionally keep information from you.

- Feeling threatened and being defensive: a nontherapeutic technique

PATIENT: All right, then: Why wouldn't that girl tell me what my blood sugar was?

NURSE: I'm not sure. If I were you, I'd forget about it and get a fresh start.

- Giving advice and using cliché, which is nontherapeutic; would have been better to acknowledge that patient had a right to know the information

NURSE: I'm going to test your blood sugar levels in a minute, and I'll tell you the results. [Performs test] Your blood sugar level was 20.

- Providing information, demonstrating trustworthiness

PATIENT: That's up pretty high, isn't it? [Worried facial expression]

- Feeling very concerned about test results

NURSE: [Nods; long pause]

- Nonverbal affirmation, use of silence to allow patient time to absorb information and gather thoughts

PATIENT: I'm so afraid complications will set in because my blood sugar is high. [Stares out window]

- Feeling free to express deeper concerns, which are hard to face

NURSE: What kinds of things are you worried about?

- Open-ended question to elicit information

PATIENT: I could lose a leg, as my mother did. Or go blind. Or have to live hooked up to a kidney machine for the rest of my life.

NURSE: You've been thinking about all kinds of things that could go wrong, and it adds to your worry not to be told what your blood sugar is.

- Summarizing to let patient "hear" what he has communicated

PATIENT: I always think the worst. [Shakes head in exasperation]

- Expressing insight into his "inner dialogue"

NURSE: I'll pass along to the technician that it's okay to tell you your blood sugar levels. And later this afternoon, I'd like us to talk more about some things you can do to help avoid these complications and set some goals for controlling your blood sugar. [Stands up, keeps looking at patient]

- Providing information, encouraging collaboration and goal setting; giving nonverbal cue that conversation is nearing end

PATIENT: Okay, I'll see you later.

- Nonverbal communication often conveys the true meaning of a message more accurately than verbal communication.
 - Helping relationships are strengthened when the nurse demonstrates caring by establishing trust, empathy, autonomy, confidentiality, and professional competence.
 - Effective communication skills are facilitative and tend to encourage the other person to openly express ideas, feelings, or concerns.
 - Ineffective communication techniques are inhibitive and tend to block the other person's willingness to openly express ideas, feelings, or concerns.
 - The nurse must blend social and informational interactions with therapeutic communication skills so that other people can explore feelings and manage health issues.
 - Older adult patients with sensory, motor, or cognitive impairments require the adaptation of communication techniques to compensate for their loss of function and special needs.
 - Patients with impaired verbal communication require special consideration and alterations in communication techniques to facilitate the sending, receiving, and interpreting of messages.
 - Desired outcomes for patients with impaired verbal communication include increased satisfaction with interpersonal interactions, the ability to send and receive clear messages, and attending to and accurately interpreting verbal and nonverbal cues.
- Jan, a nurse colleague of Mary Ellen, is having difficulty interacting assertively with Dr. Fielding, a physician who has an abrupt, intimidating communication style. Jan frequently complains of tension headaches, pent-up anger, and crying easily. What can Mary Ellen do to help Jan?
 - Mr. Hess, a patient with Parkinson's disease living at a long-term care facility, has a stiff, expressionless face as a result of his disease. He sits slumped in a recliner chair all day and seems lost in his own world, rarely looking at or interacting with anyone. When he does talk, he mumbles in a soft voice, and his words are difficult to understand. What communication skills would support your relational practice with Mr. Hess?
 - Ms. Velma Eberhard, a member of a Hutterite colony in western Canada, is considering whether she should have her two young children immunized before they begin attending school. What communication skills could you use to help her decide, and what traps must you avoid in communication about information and decision making?
 - Ms. Esther Simons, a patient who is receiving palliative care, confides in you that she feels overwhelmed with the number of issues she must attend to, now that she's facing the possibility of death. She says, "My thoughts are all over the place. I don't know where to start." What communication skills, based on the critical thinking model, can you use to help her at this point?

❖ CRITICAL THINKING EXERCISES

- Ms. Mary Goodrunning, an Aboriginal Canadian of Chipewyan descent, must learn how to manage her diabetes mellitus and self-administer insulin injections. Considering the elements of critical thinking for communication, what communication approaches and skills could you use to help her?

❖ REVIEW QUESTIONS

- Communication is not about the message that was intended but rather the message that was received and experienced in relation to each other. The statement that best helps explain this is as follows:

1. Clear communication can ensure the patient will receive the message intended.
 2. Authenticity in communication is the responsibility of the sender and the receiver.
 3. Attention to personal space (physically and emotionally) can minimize misinterpretation of communication.
 4. Contextual factors, such as attitudes, values, beliefs, and self-concept, influence relational capacity and communication.
2. As a nurse, you would demonstrate active listening by
 1. Agreeing with the patient
 2. Repeating everything the patient says to clarify
 3. Assuming a relaxed posture, establishing eye contact, and leaning toward the patient
 4. Smiling and nodding continuously throughout the interview
 3. During the orientation phase of the helping relationship, you might
 1. Discuss the cards and flowers in the room
 2. Work together with the patient to establish goals
 3. Review the patient's history to identify possible health concerns
 4. Use therapeutic communication to manage the patient's confusion
 4. If you are working with a patient who has expressive aphasia, it would be most helpful for you to
 1. Ask open-ended questions
 2. Speak loudly and use simple sentences
 3. Allow extra time for the patient to respond
 4. Encourage a family member to answer for the patient
 5. The statement that best explains the collaboration with other members of the health care team for the patient's plan of care is that the nurse
 1. Collaborates with colleagues and the patient's family to provide combined expertise in planning care
 2. Consults the physician for direction in establishing goals for patients
 3. Depends on the latest literature to complete an excellent plan of care for patients
 4. Works independently to plan and deliver care and does not depend on other staff for assistance
 6. "I'm not sure I understand what you mean by 'sicker than usual.' What is different now?" This statement reflects the therapeutic technique of
 1. Paraphrasing
 2. Providing information
 3. Clarifying
 4. Focusing
 7. "We've talked a lot about your medications, but let's look more closely at the trouble you're having in taking them on time." In this situation, you would be using the therapeutic communication skill of
 1. Paraphrasing
 2. Providing information
 3. Clarifying
 4. Focusing
 8. As a nursing student, you give yourself positive messages regarding your ability to do well on a test. This type of communication is
 1. Public
 2. Intrapersonal
 3. Interpersonal
 4. Transpersonal
 9. When working with an older adult, you should remember to avoid
 1. Touching the patient
 2. Shifting from subject to subject
 3. Allowing the patient to reminisce
 4. Asking the patient how he or she feels
 10. You should consider zones of personal space and touch when caring for patients. While there are distinctions based on unique circumstances, as a general professional practice, if you are taking the patient's health history, you should be
 1. 0 to 45 cm from the patient
 2. 45 cm to 1 m from the patient
 3. 1 to 4 m from the patient
 4. 4 m or farther from the patient

Caring in Nursing Practice

Original chapter by Anne Griffin Perry, RN, EdD, FAAN

Canadian content written by Cheryl Sams, RN, MSN

objectives

Mastery of content in this chapter will enable you to:

- Define key terms listed.
- Discuss the role that caring plays in building a nurse–patient relationship.
- Compare and contrast theories on the concept of caring.
- Discuss potential implications when nurses' perceptions of caring differ from the patients' perceptions of caring.
- Explain how an ethic of care influences nurses' decision making.
- Describe ways to express caring through presence and touch.
- Describe the therapeutic benefit of listening to patients.
- Explain the relationship between knowing a patient and clinical decision making.

key terms

Caring, p. 262
Comfort, p. 268
Cultural aspects of care,

Caring is a central concept that is essential to the practice of nursing. It is of even greater importance because of today's increasingly hectic health care environment. The demands, pressure, and time constraints in the health care environment leave little room for caring practice; as a result, nurses and other health care providers may become cold and indifferent to patients' needs (Watson 2006a, 2009). Cara (2003) believed that the current health care climate, with its emphasis on restructuring, threatens to dehumanize patient care. She stressed that the nursing profession must ensure that caring continues to be a strong force within all areas of nursing: in the clinical, administrative, educational, and research fields. The increasing use of technological advances for rapid diagnosis and treatment often causes nurses and other health care providers to perceive their relationship with patients as relatively unimportant.

Technological advances become dangerous without a context of skillful and compassionate care.

Caring practices have been evolving and are an integral part of nursing in Canada. This evolution is a complex one, and there are many influences on the development of caring. Nursing education curricula that support caring practices are essential in order for the evolution to continue. There is a direct relationship between caring and power. Traditionally, nursing has been dominated by the medical model, which was predominantly male, and caring was considered to be innate women's work (Falk, 1996). Nursing curricula were set by medical staff and hospital administrators, and the concept of caring did not require knowledge or power; thus, it was not included in any course of study. In the 1970s, hospital nursing schools were moved to colleges, and nursing was able to develop its own nursing curricula with its own power based on knowledge and expertise (Anthony & Landeen, 2009). The humanistic educative paradigm was developed and the Bevis and Watson (1989) Caring Curriculum came about. This curriculum is an empowerment model that values caring practices. The Caring Curriculum has continued to evolve and to further caring practices through nursing scholarship (Lewis et al., 2006).

Caring practices and expert knowledge that are at the heart of competent nursing practice must be valued and embraced (Benner & Wrubel, 1989; Lesniak, 2005). When you engage patients in a caring and compassionate manner, you learn that therapeutic gains in the health and well-being of your patients are enormous.

Think about your own experiences of being ill or having a problem that necessitated health care intervention. Consider the following two scenarios, and select the situation that you believe most successfully demonstrates a sense of caring.

A nurse enters a patient's room, greets the patient warmly while touching the patient lightly on the shoulder, makes eye contact, sits down for a few minutes, and asks about the patient's thoughts and concerns. The nurse listens to the patient's story, looks at the intravenous solution being administered, briefly examines the patient, and then checks the vital sign summary on the bedside computer screen before departing the room.

A second nurse enters the patient's room, looks at the intravenous solution being administered, checks the vital sign summary sheet on the bedside computer screen, and acknowledges the patient but never sits down or touches the patient. The nurse makes eye contact from above while the patient is in the vulnerable horizontal position. The nurse asks a few brief questions about the patient's symptoms and then leaves.

The first scenario depicts the nurse in specific acts of caring. The nurse's calm presence, parallel eye contact, attention to the patient's concerns, and physical closeness all express a patient-centred, comforting approach. In contrast, the second scenario is task-oriented and expresses a sense of indifference to the patient's concerns. During times of illness or when a person seeks the professional guidance of a nurse, caring is essential in helping the individual reach positive outcomes.

Theoretical Views on Caring

Caring is a universal phenomenon influencing the ways in which people think, feel, and behave in relation to one another. Since Florence Nightingale, nurses have studied caring from a variety of philosophical and ethical perspectives. A number of nursing scholars developed theories about caring because of

its importance to the practice of nursing. This chapter does not detail all theoretical positions on caring, but it helps you understand why caring is at the heart of your ability to work with all patients in a respectful and therapeutic way.

Caring Is Primary

Benner (1984) and Benner and Wrubel (1989) offered nurses a rich, holistic understanding of nursing practice and caring through interpretation of expert nurses' stories. After listening to nurses' stories and analyzing their meaning, Benner described caring as the essence of professional nursing practice. The stories revealed nurses' behaviour and decisions that expressed caring. **Caring** means concern about a person, events, projects, and things (Benner & Wrubel, 1989). It is a word for being connected.

Caring reflects what matters to a person; it describes a wide range of involvements, from parental love to friendship, from caring for one's work to caring for one's pet, to caring for and about one's patients. Benner and Wrubel (1989, p. 1) noted, "Caring creates possibility." Personal concern for another person, an event, or a thing provides motivation and direction for people to care. Caring as a framework has practical implications for transforming nursing practice (Boykin et al., 2003). The ethic of caring must be learned experientially by the nurse and leads to a skilled knowledge on how to relate to others' concerns with a respectful, responsive, and supportive approach (Benner et al., 2009). Caring is an inherent feature of nursing practice whereby nurses help patients recover from illness, give meaning to that illness, and maintain or re-establish connection with other people. Caring helps nurses identify successful interventions, and this concern then guides future caregiving.

Each individual patient has a unique background of experiences, values, and cultural perspectives. As you acquire more experience, caring helps you focus on the patients for whom you are caring. Caring facilitates your ability to understand a patient, enabling you to recognize a patient's problems and to find and implement individualized solutions.

In addition to their work in understanding caring, Benner and Wrubel (1989) described the relationship between health, illness, and disease. Health is not the absence of illness, nor is illness identical to disease (see Chapter 1 for further information). Health is a state of being that people define in relation to their own values, personality, and lifestyle. Health exists along a continuum. Illness is the experience of loss or dysfunction, whereas disease is manifested as abnormality at the cellular, tissue, or organ level. Some patients have a disease (e.g., arthritis or diabetes) but do not experience the sense of being ill or a decrease in function. Some individuals do not seek health care until they experience a disruption, loss, or concern. For example, a patient who has had diabetes for a number of years may not sense being ill until the disease causes serious visual impairment, which threatens the ability to work. Illness therefore has meaning only within the context of the person's life.

Because illness is the human experience of loss or dysfunction, any treatment or intervention given without consideration of its meaning to an individual is likely to be worthless. Expert nurses understand differences between health, illness, and disease. Through caring relationships, you learn to listen to patients' stories about their illness so that you obtain an understanding of the meaning of illness to them. With this understanding, you provide therapeutic, patient-centred care.

The Essence of Nursing and Health

From a **transcultural** perspective, Leininger (1978) described the concept of care as the essence and the central, unifying, and dominant domain that distinguishes nursing from other health disciplines. Care is an essential human need, necessary to the health and survival of all individuals. Care, unlike cure, assists an individual or group in improving a human condition. Acts of caring are nurturant and skillful activities, processes, and decisions to assist people in ways that are empathetic, compassionate, and supportive. An act of caring is dependent on needs, problems, and values of patients. Leininger's studies of numerous world cultures have revealed that care helps protect, develop, and nurture people and enable them to survive. Care is vital to recovery from illness and to maintenance of healthy life practices in all cultures.

Leininger (1988) stressed the importance of understanding cultural caring behaviours and other **cultural aspects of care**. Even though caring is a universal phenomenon, expressions, processes, and patterns of caring vary among cultures (Box 18-1). Caring is very personal, and expressions of caring differ for each patient. For caring to be effective and meaningful to patients, you need to learn culturally specific behaviours and words that reflect human caring in different cultures. Refer to Chapter 9 for more information on culture and ethnicity.

Transpersonal Caring

Patients and their families should receive high-quality human interaction with nurses. Unfortunately, many conversations

occurring between patients and their nurses are brief and disconnected. According to Watson's (1979, 1988, 2008) theory of caring (a holistic nursing model), a conscious intention to care promotes healing and wholeness (Hoover, 2002). This intention is complementary to conventional science and modern nursing practices. Theory integrates human caring processes with healing environments, incorporating life-generating and life-receiving processes of human caring and healing for both nurses and their patients (Watson, 2006b). The theory describes a consciousness that allows nurses to raise new questions about what it means to be a nurse, what it means for a patient to be ill, and how caring and healing should take place. Transpersonal caring theory rejects the disease orientation of health care and stresses care as more important than cure (Watson, 1988). Instead of focusing on the patient's disease and its treatment by conventional means, transpersonal caring explores inner sources of healing to protect, enhance, and preserve a person's dignity, humanity, wholeness, and inner harmony.

In Watson's (2006b) view, caring is almost spiritual. Caring preserves human dignity in the technological, cure-dominated health care system. The emphasis is on the nurse-patient relationship, as well as the caring relationship. During a single caring moment between the nurse and patient, the nurse and patient may communicate to each other on a level deeper than simple verbal exchange. There may be a sense of connection between the one cared for and the one caring. Caring on a deep, interpersonal level can promote healing (Watson, 2006b). The application of Watson's caring model may enhance your caring practices. The model is **transformative** because the relationship influences both nurses and patients, for better or for worse (Hoover, 2002). Watson further developed her caring science theory, and her carative factors are now called *carative processes* and are outlined in Table 18-1. Evidence-informed material that enhances caring is described in Box 18-2.

Swanson's Theory of Caring

In an effort to develop a theory of caring applicable for nursing practice, Swanson (1991) studied patients and professional caregivers. Three different groups were interviewed: women who miscarried, parents and health care providers in a neonatal intensive care unit, and socially at-risk mothers who had received long-term, public health intervention. All groups were interviewed before, during, or after labour and delivery of a child and had experienced the phenomenon of caring. Researchers asked each subject questions regarding how they experienced caring in their situation. After analyzing the stories and descriptions of three research groups, Swanson developed a theory of caring, whereby caring consists of five categories or processes: knowing, "being with," "doing for," enabling, and maintaining belief (Table 18-2).

Swanson's (1991) contributions are valuable in providing direction for how to develop useful and effective caring strategies. Each process is crucial in making positive differences in patients' health and well-being outcomes. Research findings used to develop the theory are useful in guiding clinical nursing practice. For example, Swanson (1999) tested the effects of caring-based counselling on women's emotional well-being in the first year after the miscarriage. Caring-based counselling was significant in reducing women's depression and anger, particularly during the first four months after the miscarriage.

BOX 18-1 CULTURAL ASPECTS OF CARE

Nurse Caring Behaviours

As a nurse, you must provide caring behaviours that are based on patients' cultural values and beliefs. Although the need for human caring is universal, its application is based on cultural norms. For example, providing time for family presence is often more valuable to traditional Asian families than is nursing presence. Using touch to convey caring sometimes crosses cultural norms. Sometimes gender-congruent caregivers or patients' family need to provide caring touch. In some cultures, maintaining eye contact while listening to the patient is considered disrespectful.

Implications for Practice

- Know patient's cultural norms for caring practices.
- Know patient's cultural practices regarding end-of-life care. In some cultures, it is considered insensitive to tell patients that they are dying.
- Determine whether a member of patient's family or cultural group is most appropriate resource for presence or touching.
- Determine the need for gender-congruent caregivers.
- Avoid use of idioms because they can often create misunderstanding between the caregiver and the patient or family.
- Know patient's cultural practices regarding removal of life support.

▶ TABLE 18-1 Watson's Carative Processes

Carative Factors or Caritas Processes**Description**

Humanistic–altruistic values	Practising loving-kindness and equanimity for self and others
Instilling or enabling faith and help	Being authentically present: enabling, sustaining, and honouring deep belief system and subjective world of self and others
Cultivating sensitivity to oneself and others	Cultivating one's own spiritual practices; deepening self-awareness, going beyond "ego-self"
Developing a helping–trusting, human caring relationship	Promoting and supporting a relationship that is characterized by trust, authenticity, helping, and caring
Promoting and accepting expression of positive and negative feelings	Being present to and supportive of expression of positive and negative feelings, recognizing both as important to a deep, interpersonal connection between self and person being cared for
Systematic use of scientific (creative) problem-solving process	Creatively using self and all ways of knowing, being, and doing as part of caring process (engaging in artistry of caring–healing practices)
Providing for a supportive, protective, or corrective mental, social, spiritual environment	Creating healing environment at all levels: physical and nonphysical, whereby wholeness, beauty, comfort, dignity, and peace are potential (being or becoming the environment)
Assisting with gratification of human needs	Reverentially and respectfully assisting with basic needs; holding an intentional, caring consciousness of touching and working with the embodied spirit of another; honouring a sense of unity within oneself; allowing for spirit-filled connection
Allowing for existential–phenomenological dimensions	Being open-minded and attending to spiritual, mysterious, unknown existential dimension of life, death, and suffering: "allowing for a miracle"

The Human Act of Caring

Roach (1997) also focused on the integration of caring and spirituality in her "human act of caring" theory. She was requested by the Canadian Nurses Association (CNA) in 1977 to develop the first Canadian code of ethics for Canadian nurses. This first code was based on her caring theory, which

* BOX 18-2

EVIDENCE-INFORMED PRACTICE GUIDELINE**Enhancing Caring****Evidence Summary**

Caring facilitates healing and improves patient satisfaction with nursing care. However, does the instructional process influence human caring? Do nurse educators present instructional methods that improve students' caring practices? In Hoover's (2002) study, undergraduate nursing students attended a 15-week educational module on nursing as human caring. The purpose of the module was to improve students' understanding of caring practice and to thus make them more caring practitioners. Researchers interviewed students before and after completing the module to understand the effects of this module on their caring practices. They asked students about factors that facilitate and impede their caring practices. Students reported an increase in self-awareness in regard to (1) connecting in relationships with self and others, (2) finding purpose and meaning in life, and (3) clarifying values. Several students spoke of becoming more tolerant of others, recognizing each person's uniqueness, and appreciating a person's perspectives. By recognizing themselves as caring persons, students gained meaning in their lives. Many were able to report a great deal of satisfaction in recognizing that they were caring persons and how nursing allowed them to express that characteristic. Students worked through the emotional issues and practical constraints, which allowed them to grow spiritually and connect with patients at a deeper level. Finally, students also expressed an enhanced appreciation of what they valued.

**Application to Nursing Practice**

- Increasing knowledge and understanding of caring helps nurses begin to understand patients' worlds and to change their approach to nursing care.
- Use of caring in nursing practice encourages a more holistic approach to nursing care.
- As nurses use caring, they get to know their patients and therefore better meet their needs.
- The caring model involves closeness, commitment, and involvement in the nurse–patient relationship.

Source: Hoover, J. (2002). The personal and professional impact of undertaking an educational module on human caring. *Journal of Advanced Nursing*, 37(1), 79–86.

comprised five concepts: compassion, competence, confidence, conscience, and commitment (Table 18-3). This foundational work set the stage for a value-based code that has been updated over time but continues to retain Roach's caring principles as the framework (Storch, 2007). The CNA (1997) *Code of Ethics for Registered Nurses* was revised and published in 2008.

Pusari (1998) applied Roach's theory in work with people with life-threatening illnesses. She proposed that Roach's caring elements be extended to include the concepts of courage, culture, and communication; thus, the theory would be more holistic. These eight concepts incorporate physical, psychological, emotional, spiritual, and cultural components to guide nurses as they provide comprehensive and individualistic care.

► TABLE 18-2 Swanson's Theory of Caring

Caring Process	Definitions	Subdimensions
Knowing	Striving to understand an event as it has meaning in the life of the other person	Avoiding assumptions about the life of the other person Centring on the one cared for Seeking cues
"Being with"	Being emotionally present for the other person	Engaging the self or both the self and the other person "Being there" Conveying ability Sharing feelings
"Doing for"	Doing for (assisting) the other person with actions that he or she would do for himself or herself if it were at all possible	Not burdening Comforting Anticipating Performing skillfully Protecting
Enabling	Facilitating the other person's passage through life transitions (e.g., birth, death) and unfamiliar events	Preserving dignity Informing and explaining Supporting and allowing Focusing Generating alternatives
Maintaining belief	Sustaining faith in the other person's capacity to get through an event or transition and face a future with meaning	Validating and giving feedback Believing in and holding in esteem Maintaining a hope-filled attitude Offering realistic optimism Spending extra effort to help the other person

From Swanson, K. M. (1991). Empirical development of a middle-range theory of caring. *Nursing Research*, 40(3), 161–166.

► TABLE 18-3 The Human Act of Caring

Compassion	- Way of living born out of an awareness of one's relationship to all living creatures - Engendering a response of participation in the experience of another - A sensitivity to the pain and brokenness of the other; a quality of presence that allows one to share with and make room for the other
Competence	State of having the knowledge, judgement, skills, energy, experience, and motivation required to respond adequately to the demands of one's professional responsibilities
Confidence	- Quality that fosters trusting relationships - Goals of service rendered within an environment and under conditions of mutual trust and respect
Conscience	- State of moral awareness - Compass directing one's behaviour according to the moral fitness of things
Commitment	Complex affective response characterized by a convergence between one's desires and one's obligations and by a deliberate choice to act in accordance with them

From Roach, S. (1992). *The human act of caring. A blueprint for the health professions*. Ottawa: Canadian Hospital Association.

Summary of Theoretical Views

Nursing caring theories have common themes. Caring is highly relational. Caring relationships open up possibilities (e.g., for comfort, touch, and solace) or close them down (Benner, 2004). Nurses and patients enter into a relationship that is much more than one person simply "doing tasks for" another. A mutual give-and-take develops as nurse and patient begin to know and care for one another. In his own experience with cancer, sociologist Arthur Frank (1998) noted that what he wanted when he was ill was a mutual relationship with persons who were also clinicians and patients. It was important for Frank to be seen as one of two fellow human beings, not the dependent patient being cared for by the expert technical clinician.

Caring seems highly invisible at times when a nurse and patient enter a relationship of respect, concern, and support. The nurse's empathy and compassion become a natural part of every patient encounter. Absence of caring, however, is very obvious. For example, if nurses show a lack of interest or choose to avoid a patient's request for help, the nurses' inactions quickly convey an uncaring attitude. Benner and Wrubel (1989, p. 14) related the story of a clinical nurse specialist who learned from a patient what caring is all about: "I felt that I was teaching him a lot, but actually he taught me. One day he said to me (probably after I had delivered some well meaning technical information about his disease), 'You are doing an OK job, but I can tell that every time you walk in that door you are walking out.'" In this nurse's story, the patient perceived that the nurse was simply going through the motion of teaching and showed little caring toward the patient. Patients quickly sense nurses' failure to empathize with them.

The Moral and Ethical Bases of Responsive Nurse-Patient Relationships

Tarlier (2004), a Canadian author, presented another perspective on the principle of caring as a foundational nursing concept: that the concept of caring has not been well defined and that the nursing ethic of caring must be empirically shown to make a difference in patient outcomes. For the nursing profession, it is important to provide evidence that caring is tied to a broader ethical knowledge base.

A personal moral sense that is shared by other people needs to be agreed on as a principle and integrated specifically into the discipline of nursing and the nursing ethical knowledge base. Tarlier (2004) put forward the idea of responsive nurse-patient relationships that are conceptualized in the nursing literature. Responsive relationships are based on respect, trust, and mutuality. These relationships can tie together theory, ethical knowledge, and clinical outcomes and strengthen the nursing ethical knowledge base.

With a caring nurse, the patient senses commitment on the part of the nurse and is willing to allow the nurse to gain an understanding of the patient's experience of illness. In a study of oncology patients' descriptions of their nursing care, Radwin et al. (2005, p. 166) found that patients characterized a caring nurse as one who would "quietly try to care for every need I had" and "be there when you need them" versus "treat[ing] you like a number or a case rather than a person." You become a coach and partner rather than a detached provider of care.

Imagine a nurse is working with a patient who recently was diagnosed with diabetes mellitus and who must learn to administer daily insulin. In this scenario, the nurse's caring behaviour might be enabling. When a nurse practises enabling, the patient and nurse work together to identify treatment alternatives and resources. The nurse enables the patient to understand diabetes management, and the nurse supports the patient in progressing through self-care activities.

Another common theme in caring is to understand the context of the patient's life and illness. It is difficult to demonstrate caring without gaining an understanding of who the other person is and that person's perception of his or her illness. By exploring the following questions with the patient, you can begin understanding the patient's perception of illness: "How was your illness first recognized?" "How do you feel about the illness?" "How does the illness affect your daily life practices?" Knowing the context of a patient's illness helps you choose and individualize interventions that will actually help the patient. This approach is more successful than simply selecting interventions on the basis of the patient's symptoms or disease process.

Patients' Perceptions of Caring

Swanson's (1991) theory of caring is a foundation for understanding behaviours and processes that characterize caring. Other researchers have also studied caring from patients' perceptions (Table 18-4). Identifying nurse behaviours that patients perceive as caring helps nurses understand what patients expect of them as caregivers. Patients continue to value nurses' effectiveness in performing tasks and clearly also value the affective dimension of nursing care (Williams, 1997): establishing a reassuring presence, recognizing an individual as unique, and being attentive to patients. Each patient has a

unique background of experiences, values, and cultural perspectives; however, understanding common behaviours that patients associate with caring helps you learn to express caring in practice.

The study of patients' perceptions is important because health care emphasizes patient satisfaction. What patients experience in their interactions with institutional services and health care providers, and what they think of that experience, determines how patients use the health care system and how they can benefit from it (Gerteis et al., 1993; Mayer, 1986). When patients believe that health care providers are sensitive, sympathetic, compassionate, and interested in them as people, they usually become active partners in the plan of care (Attree, 2001). Williams (1997) studied relationships between patients' perceptions of four dimensions of caring and their satisfaction with nursing care. Patients indicated that they were more satisfied when they perceived nurses to be caring. Radwin (2000) found that oncology patients associated excellent nursing care with attentiveness, partnership, individualization, rapport, and caring. As institutions look to improve patient satisfaction, creating a caring environment is a necessary and worthwhile goal. Patients' satisfaction with nursing care is an important factor in their decision to return to a hospital.

As a new clinical practitioner, you must account for how patients perceive caring and the best approaches to providing care. To start, consider behaviours associated with caring and consider an individual patient's perceptions and unique expectations. Patients and nurses frequently differ in their perceptions of caring (Mayer, 1987; Wolf et al., 2003). Consider the situation in which your patient is fearful of having an intravenous catheter inserted, and you are still a novice at catheter insertion. Instead of giving a lengthy description of the procedure to relieve the patient's anxiety, you decide the patient will benefit more if you obtain assistance from a skilled staff member. Understanding patients' perceptions helps you select caring approaches that are most appropriate to the patients' needs.

Ethic of Care

Caring is a moral imperative. Through caring for others, human dignity is ultimately protected, enhanced, and preserved. Watson (1988) suggested that caring, as a moral ideal,

► TABLE 18-4 Comparison of Research Studies Exploring Patients' Perceptions of Nurse Caring Behaviour

WOLF ET AL. (2003)		ATTREE (2001)	CHANG ET AL. (2005)
Patients With Cardiac Conditions	Male Patients	General Medical Patients and Families	Patients With Cancer
Managing equipment skillfully	Being physically present so that patient feels valued	Checking up on patient	Being accessible to patient and family
Being perceptive and compassionate	Returning voluntarily without being called	Being compassionate and patient	Providing comfort
Being physically present	Making patient feel comfortable, relaxed, and secure	Demonstrating sensitivity and sympathy	Being trustworthy
Using a soft, gentle voice	Attending to comfort and needs of patient before performing tasks	Using a calm, gentle, and kind approach	Anticipating patient and family needs
Returning to patient voluntarily without being asked	Using a kind, soft, pleasant, gentle voice and attitude		
Providing comfort and security			
Helping reduce pain			

provides the stance from which a nurse intervenes and ensures the practice of ethical standards for good conduct, character, and motives. Chapter 7 explores the importance of ethics in professional nursing. The term *ethic* refers to the ideals of right and wrong behaviour. In any patient encounter, a nurse needs to know what behaviour is ethically appropriate. An **ethic of care** ensures that nurses do not make decisions solely on the basis of intellectual or analytical principles and places caring at the centre of decision making. For example, consider whether placing a disabled relative in a long-term care facility is truly caring.

An ethic of care is concerned with relationships between people and with a nurse's character and attitude toward others. Nurses who function according to an ethic of care are sensitive to unequal relationships that can lead to an abuse of one person's power over another, intentional or otherwise. In health care settings, patients and families are often on unequal footing with professionals because of patients' illness, lack of information, regression caused by pain and suffering, and unfamiliar circumstances. According to an ethic of care, the nurse is the patient's advocate, solving ethical dilemmas by attending to relationships and by recognizing each patient's uniqueness as a human being.

Caring in Nursing Practice

It is impossible to prescribe ways that will guarantee whether or when a nurse becomes a caring professional. Experts disagree as to whether caring is teachable or fundamentally a way of being. Cook and Cullen (2003) wrote about the importance of teaching caring as an integral part of a nursing curriculum. In order for the value of caring to be internalized by student nurses, caring behaviours must be demonstrated, and clinical opportunities to practise these behaviours must be built into the program. Caring models are essential to help in the development of a student's capacity to care (Roach, 1992). For example, Watson's nursing model has been adopted by many nursing programs in which the concept of caring is integrated throughout the curriculum.

For people who view caring as a normal part of their lives, caring is a product of their cultures, values, experiences, and relationships with other people. Persons who do not experience care in their lives often find it difficult to act in caring ways. As nurses deal with health and illness in their practice, their ability to care grows. Nursing behaviours that show caring include providing presence, a caring touch, and listening in each encounter with patients.

Providing Presence

Providing **presence** is to have a person-to-person encounter that conveys closeness and a sense of caring. Fredriksson (1999) explained that presence involves "being there" and "being with." "Being there" is not only physical presence but also communication and understanding. The interpersonal relationship of "being there" seems to depend on the fact that a nurse is attentive to the patient (Cohen et al., 1994). You offer this type of presence to the patient with the purpose of achieving some goal, such as support, comfort, or encouragement; to diminish the intensity of unwanted feelings; or for reassurance (Fareed, 1996; Pederson, 1993).

"Being with" is also interpersonal. It means being available and at your patients' disposal (Pederson, 1993). If patients accept the nurse, they will invite the nurse to see and share

their vulnerability and suffering. One person's human presence never leaves another person unaffected (Watson & Foster, 2003). The nurse then enables the patient to articulate his or her feelings and to understand himself or herself in a way that leads to identifying solutions, seeing new directions, and making choices (Gilje, 1997).

By establishing presence—through eye contact, body language, voice tone, listening, and having a positive and encouraging attitude—you create openness and understanding. The message conveyed this way is that the patient's experience matters to you (Swanson, 1991). Establishing presence with a patient enhances your ability to learn from the patient, which enhances nursing care.

It is especially important to establish presence when patients are experiencing stressful events or situations. Awaiting a physician's report of test results, preparing for an unfamiliar procedure, and planning to return home after a serious illness are just a few events in the course of a person's illness that can create unpredictability and dependency on health care providers. Your presence can help calm a patient's anxiety and fear in such situations. Giving reassurance and thorough explanations about a procedure, remaining at the patient's side, and coaching the patient through the experience all convey caring, which is invaluable to the patient's well-being.

Touch

Patients face situations that can be embarrassing, frightening, and painful. Whatever the feeling or symptom, patients look to nurses for **comfort**. Touch is one comforting approach in which the nurse communicates concern and support.

Touch is relational and leads to a connection between nurse and patient. Touch involves contact (physical) and noncontact touch. Contact touch involves obvious skin-to-skin contact, whereas noncontact touch refers to eye contact. It is difficult to separate the two. Both are described within three categories: task-orientated touch, caring touch, and protective touch (Fredriksson, 1999).

Nurses use task-orientated touch when performing a task or procedure. Skillful and gentle performance of a nursing procedure conveys security and a sense of competence. An expert nurse learns that any procedure is more effective when administered carefully and with consideration for any patient concern. For example, if a patient is anxious about a procedure such as an insertion of a nasogastric tube, the nurse provides comfort through full explanation of the procedure and what the patient will feel. The nurse then assures the patient that the procedure will be performed safely, skillfully, and successfully. This assurance is conveyed in the way that supplies are prepared, the patient is positioned, and the nasogastric tube is gently manipulated and inserted. Throughout the procedure, the nurse talks quietly with the patient to provide reassurance and support.

Caring touch is a form of nonverbal communication that successfully influences a patient's comfort and security, enhances self-esteem, and improves reality orientation (Boyek & Watson, 1994). The nurse can express this caring touch by holding a patient's hand, by giving the patient a back massage, by gently positioning a patient, or by participating in a conversation. When using a caring touch, the nurse is making a connection by showing acceptance of the patient (Tommasini, 1990).

Protective touch is a form of touch that protects the nurse, the patient, or both. The patient views it either positively or

negatively. The most obvious form of protective touch is in preventing an accident, such as holding and bracing the patient to avoid a fall. This protects the patient. Sometimes nurses withdraw from a patient or distance themselves when they are unable to tolerate suffering or need to escape from a tense situation. This protects the nurse but elicits negative feelings in a patient (Fredriksson, 1999).

Because touch conveys many messages, it must be used with discretion. Touch itself is a concern when crossing cultural boundaries of either patients or nurses (Benner, 2004). Patients generally permit task-orientated touch because most individuals give nurses and doctors authority to enter their personal space to provide care. However, exceptions can exist because of patients' cultural backgrounds. You should understand whether patients are accepting of touch and how they interpret your intentions.

Listening

Caring involves an interpersonal interaction that is much more than two people simply talking back and forth. In a caring relationship, the nurse establishes trust, opens lines of communication, and listens to the patient (Figure 18-1). Listening is key, because it conveys the nurse's full attention and interest. Listening includes "taking in" what a patient says, as well as interpreting and understanding what the patient is saying and conveying that understanding to the person talking (Kemper, 1992). Listening to the meaning of what a patient says helps create a mutual relationship. True listening leads to truly knowing and responding to what really matters to the patient and family (Boykin et al., 2003).

When an individual becomes ill, he or she usually has a story to tell about the meaning of the illness. Any critical or chronic illness affects all of a patient's life choices and decisions and sometimes the individual's identity. Being able to tell that story helps the patient deal with the distress of illness. Thus, a story needs a listener. Frank (1998) described his own feelings during his experience with cancer, saying that he needed a health care provider's gift of listening in order to make his suffering a relationship between them instead of an iron cage around him. He needed to be able to express what he needed when he was ill. Personal concerns that are part of a patient's illness story are what is at stake for the patient. Caring through listening enables the nurse to be a participant in the patient's life.

Figure 18-1 Nurse listening to a patient.

To listen effectively, listeners need to silence themselves (Fredriksson, 1999). Fredriksson described silencing one's mouth and also one's mind: that is, to silence one's own thoughts that might distract from fully listening to a patient. It is important to remain intentionally silent and to concentrate on what patients have to say. You need to be able to give patients your full, focused attention as they tell their stories.

When an ill person chooses to tell his or her story, it involves reaching out to others. Telling the story implies a relationship that can develop only if the clinician exchanges his or her stories as well. Frank (1998) argued that professionals do not routinely take seriously their own need to be known as part of a clinical relationship. Yet, unless professionals acknowledge this need, the relationship is not reciprocal; it is only an interaction (Campo, 1997). The clinician is pressured to know as much as possible about the patient, but this pressure isolates the clinician from the patient. In contrast, in knowing and being known, each supports the other (Frank, 1998).

Through active listening, you begin to truly know the patient and what is important to him or her (Bernick, 2004). Learning to listen to a patient is sometimes difficult. It is easy to become distracted by tasks at hand, colleagues shouting instructions, or other patients waiting to have their needs met. However, the time you take to listen is worthwhile both in the information gained and in the strengthening of the nurse-patient relationship. Listening involves paying attention to the individual's words and tone of voice and understanding his or her perspective. Chapter 17 provides more detailed information on the art of communication. By observing the expressions and body language of the patient, you will find cues to help assist the patient in exploring ways to achieve a greater sense of peace and well-being.

Knowing the Patient

One of the five caring processes described by Swanson (1991) is knowing the patient. This concept comprises both your understanding of a specific patient's situation and your subsequent selection of interventions (Radwin, 1995). Knowing develops over time as you learn the clinical conditions within a specialty and the behaviours and physiological responses of patients. Intimate knowing helps you respond to what really matters to the patient (Bulfin, 2005). To know a patient means that you avoid assumptions, focus on the patient, and engage in a caring relationship with the patient so that you can detect information and cues that facilitate critical thinking and clinical judgements (see Chapter 7 for further details on nursing values and ethics). Knowing that the patient is at the core of the process, you use this process to make clinical decisions. By establishing a caring relationship, you develop the understanding that helps you better know the patient as a unique individual and choose the most appropriate and helpful nursing therapies.

The caring relationships that you develop over time, coupled with your growing knowledge and experience, enable you to detect changes in a patient's clinical status. Expert nurses develop this ability to detect such changes almost effortlessly. Clinical decision making, perhaps the most important nursing responsibility, involves various aspects of knowing the patient: responses to therapies, routines, and habits; coping resources; physical capacities and endurance; and body typology and characteristics (Tanner et al., 1993). Experienced nurses know additional facts about their patients, such as their experiences, behaviours, feelings, and perceptions (Radwin, 1995). When you make clinical decisions accurately in the

context of knowing a patient well, patient outcomes are improved. Swanson (1999) noted that when nurses base care on knowing the patient, the patients perceived care as personalized, comforting, supportive, and healing.

The most important thing for a beginning nurse to recognize is that knowing a patient is more than simply gathering data about the patient's clinical signs and condition. Success in knowing the patient depends on the relationship you establish. To know a patient is to enter into a caring, social process that results in "bonding," whereby the patient comes to feel known by the nurse (Lamb & Stempel, 1994). The bonding then enables the relationship to evolve into "working" and "changing" phases so that you can help the patient become involved in his or her care and accept help when needed (Bulfin, 2005).

Spiritual Caring

Spiritual health occurs when a person finds a balance between his or her own life values, goals, and belief systems and those of others (see Chapter 27 for more information on spiritual health). Human beings have physical, emotional, spiritual, and psychological dimensions. An individual's beliefs and expectations do have effects on his or her physical well-being.

Establishing a caring relationship with a patient involves an interconnectedness between the nurse and the patient. This interconnectedness is why Watson (1979, 2006a, 2006b, 2008) described the caring relationship in a spiritual sense. Spirituality offers a sense of connection intrapersonally (connected with oneself), interpersonally (connected with others and the environment), and transpersonally (connected with an unseen higher power). In a caring relationship, the patient and the nurse come to know one another so that the relationship becomes one of healing through the following actions:

- Mobilizing hope for the patient and for the nurse
- Finding an interpretation or understanding of illness, symptoms, or emotions that is acceptable to the patient
- Assisting the patient in using social, emotional, or spiritual resources

Family Care

Each individual experiences life through relationships with others. Caring for an individual does not occur in isolation from that person's family. It is important for you as a nurse to know the family almost as thoroughly as they know the patient (Figure 18-2). The family is an important resource. Success with nursing interventions often depends on the family's willingness to share information about the patient, their acceptance and understanding of therapies, whether the interventions fit with the family's acceptance and understanding of therapies, whether the interventions fit with the family's daily practices, and whether the family supports and provides the therapies recommended.

Many nurse caring behaviours are perceived as most helpful by families of patients with cancer (Box 18-3). Ensuring the patient's well-being and helping the family become active participants in the patient's care are critical for family members. These behaviours, although specific to families of patients with cancer, are useful for developing a caring relationship with all families. Begin a relationship by learning who makes up the patient's family and what family members' roles are in the patient's life. Showing the family care and concern for the patient creates an openness that then enables a relationship to form with the family. Caring for the family takes into

Figure 18-2 The nurse discusses the patient's health care needs with the family.

► BOX 18-3

Nurse Behaviours Perceived by Families as Caring

- Being honest
- Giving clear explanations
- Keeping family members informed
- Trying to make the patient comfortable
- Showing interest in answering questions
- Providing necessary emergency care
- Assuring the patient that nursing services will be available
- Answering family members' questions honestly, openly, and willingly
- Allowing the patient to do as much for himself or herself as possible
- Teaching the family how to keep the patient physically comfortable

consideration the context of the patient's illness and the stress it imposes on all members. Chapter 19 contains more material on family nursing.

The Challenge of Caring

Assisting individuals during a time of need is the reason that many people enter the field of nursing. When nurses are able to affirm themselves as caring individuals, they reinforce a meaning and purpose to their lives (Benner, 2004; Hoover, 2002). Caring is a motivating force for people to become nurses, and it becomes the source of satisfaction when nurses know they have made a difference in their patients' lives.

It is becoming more of a challenge to care in today's health care system. Being a part of the helping professions is difficult and demanding. Nurses are torn between the human caring model and the task-oriented biomedical model and institutional demands that consume their practice (Watson & Foster,

2003). The time that nurses can spend with patients is diminishing, which makes it much harder to know their patients. Too often, patients are perceived as just cases, and their real needs are either overlooked or ignored. The nature of caring is undermined by reliance on technology, reliance on cost-effective health care strategies, and efforts to standardize and refine work processes. These factors can lead to an increased risk of burnout from the stress and inability to fully practise professional standards that include caring behaviours. It is very important that student and novice nurses are supported in their efforts to be patient-focused.

The CNA has partnered with the Canadian Council on Health Services Accreditation, Health Canada's Office of Nursing Policy, and other important stakeholders to research, develop, and promote quality of work-life indicators (CNA, 2002). These fundamental indicators are designed to help organizations improve the health of their work environments and are important for implementing patient-focused care, preventing burnout, and preserving the practice of caring. Providing safe, compassionate, competent, and ethical care is a hallmark of the CNA (2008) *Code of Ethics*.

The Registered Nurses' Association of Ontario (2006) developed a guideline for nursing best practices that is informed by evidence about how to provide patient-centred care. This guideline includes practice, education, organization, and policy recommendations that can help the individual nurse, educational organizations, and health care organizations implement patient-centred care and integrate the ethic of caring into practice.

If health care is to make a positive difference in their lives, human beings cannot be treated like machines or robots. Instead, health care must become more humanized. Nurses play an important role in making caring behaviours an integral part of the health care delivery. First, nurses must make caring a part of the philosophy and environment in the workplace. By incorporating care concepts into standards of nursing care, nurses establish the guidelines for professional conduct. Finally, during day-to-day practice with patients and families, nurses need to be committed to caring and be willing to establish the relationships necessary for personal, competent, compassionate, and meaningful nursing care.

✦ KEY CONCEPTS

- Caring is at the heart of a nurse's ability to work with people in a respectful and therapeutic way.
- Caring is always specific and relational for each nurse-patient encounter.
- For caring to be effective and meaningful to patients, nurses must learn culturally specific behaviours and words that reflect human caring in different cultures.
- Because illness is the human experience of loss or dysfunction, any treatment or intervention given without consideration of its meaning to the individual is likely to be worthless.
- Swanson's theory of caring includes five caring processes: knowing, "being with," "doing for," enabling, and maintaining belief.
- Roach's caring theory comprises five concepts: compassion, competence, confidence, conscience, and commitment.
- Caring involves a mutual give-and-take that develops as nurse and patient begin to know and care for one another.
- It is difficult to demonstrate caring to patients without gaining an understanding of who they are and their perception of their illness.

- Presence involves a person-to-person encounter that conveys closeness and a sense of caring that involves "being there" and "being with" patients.
- Research has shown that touch, both contact and noncontact, includes task-orientated touch, caring touch, and protective touch.
- The skillful and gentle performance of a nursing procedure conveys security and a sense of competence in the nurse.
- Listening includes interpreting and understanding what is said.
- Knowing the patient is at the core of the process by which nurses make clinical decisions.
- A nurse demonstrates caring by helping family members become active participants in a patient's care.

✦ CRITICAL THINKING EXERCISES

1. Mrs. Lowe is a 52-year-old patient being treated for lymphoma (cancer of the lymph nodes) that occurred six years after lung transplantation. Mrs. Lowe is discouraged about her current health status and a lot of what she describes as muscle pain. The unit where Mrs. Lowe is receiving care has a number of very sick patients and is short-staffed.
 - a. You enter her room to perform a morning assessment and find Mrs. Lowe crying. How are you going to use caring practices to help Mrs. Lowe, knowing that you have only begun your tasks for the day?
 - b. When you listened to Mrs. Lowe, she explained that her muscle pain was very bothersome and it was worse particularly when she was alone. Both you and Mrs. Lowe determine that an injection for her pain would be beneficial. In what way are you caring when you administer the injection to Mrs. Lowe?
 - c. Mrs. Lowe seems more comfortable and is crying less. What else can you do for Mrs. Lowe?
2. During your next clinical practicum, select a patient to talk with for at least 15 to 20 minutes. Ask the patient to tell you about his or her illness:
 - a. What do you believe the patient was trying to tell you about his or her illness?
 - b. Why was it important for the patient to share his or her story?
 - c. What did you do that made it easy or difficult for the patient to talk with you? What did you do well? What could you have done better?
 - d. Would you rate yourself a good listener? How can you listen better?

✦ REVIEW QUESTIONS

1. A nurse hears a colleague tell a student nurse that she never touches the patients unless she is performing a procedure or doing an assessment. The nurse tells the colleague that
 1. She does not touch the patients either
 2. Touch is a type of verbal communication
 3. Using touch is never a problem
 4. Touch forms a connection between nurse and patient
2. Of the five caring processes, "knowing" the patient is best described as
 1. Anticipating the patient's cultural preference
 2. Determining the patient's physician preferences
 3. Gathering task-oriented information during assessment
 4. Establishing an enhanced understanding of the patient's needs

3. Helping a new mother through the birthing experience demonstrates which of the five caring behaviours?
 1. Knowing
 2. Enabling
 3. "Doing for"
 4. "Being with"
 5. Maintaining belief
4. Mr. Kline is fearful of upcoming surgery and a possible cancer diagnosis. He discussed his love for the Bible with Jada, his nurse, and she recommends a favourite Bible verse. Another nurse tells Jada that spiritual caring has no place in nursing. Jada replies:
 1. "Spiritual care should be left to a professional."
 2. "You are correct; expressions of spirituality are a personal decision."
 3. "Nurses should not force their spiritual beliefs on patients."
 4. "Healing can be promoted by assisting the patient in using spiritual resources."
5. A number of strategies have potential for creating work environments that enable nurses to demonstrate more caring behaviours. Some of these include
 1. Increases in working hours
 2. Increases in monetary gain
 3. Flexibility, autonomy, and improvements in staffing
 4. Increases in physicians' input concerning nursing functions
6. A nurse demonstrates caring by helping family members
 1. Become active participants in care
 2. Provide activities of daily living
 3. Remove themselves from personal care
 4. Make health care decisions for the patient
7. Listening is not only "taking in" what a patient says; it also includes
 1. Incorporating the views of the physician
 2. Correcting any errors in the patient's understanding
 3. Injecting the nurse's personal views and statements
 4. Interpreting and understanding what the patient means
8. Presence involves a person-to-person encounter that
 1. Enables patients to care for themselves
 2. Provides personal care to a patient
 3. Conveys a closeness and sense of caring
 4. Describes being in close contact with a patient
9. By considering the patients' perceptions of caring, nurses are better able to
 1. Understand what patients expect of them as caregivers
 2. Be more efficient in performing tasks
 3. Provide continuity of care
 4. Establish nursing priorities

Rationales for the Review Questions appear at the end of the book.

Family Nursing

Written by Christina West, RN, PhD, and Sonya L. Jakubec, RN, MN, PhD(c)

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Discuss how the term *family* can be defined.
- Examine current trends in the Canadian family.
- Discuss how family members influence one another's health.
- Compare family as context, family as patient and family *in* context, explaining how these different perspectives influence nursing practice with families.
- State the three major categories of the Calgary Family Assessment Model (CFAM) and understand subcategories important to consider in a family assessment.
- Describe key concepts of the Calgary Family Intervention Model (CFIM).
- Discuss family nursing as relational inquiry.
- Describe key concepts and approaches to relational inquiry-based practices for family nursing.
- Ask assessment questions to learn relevant information about family functioning in the context of health or illness.
- Discuss the relational approaches and practices needed to conduct a family interview and effectively intervene with the family in nursing practice.

The role of the family in health care has evolved significantly in previous years. In the early twentieth century, visiting public health nurses and private duty nurses worked closely with family members, providing care in the patient's home. After World War II, with the development of a national health care system in Canada, the location of most nursing services shifted to hospital settings. With these historical changes in health care, families were largely excluded from their relatives' nursing care, while physicians and nurses came to be considered the experts in health care provision (Elliott et al., 2009). Tension between the role of professionals and family members in health care has persisted, although families and nurses have increasingly forged more collaborative relationships. Family nursing is a highly contextual, relational, and skill-based practice in which nurses face complex clinical situations. Within these situations, nurses need to simultaneously attend to the needs of multiple family members and complex environments, as well as the family unit (Registered Nurses' Association of Ontario [RNAO], 2006). An example of the complexity faced in present-day nursing practice would be the care

of families living in rural settings with members admitted to urban hospitals several hundred kilometres from their home (Jackman et al., 2010). The location of a patient's care may create significant challenges for the family in relation to travel, employment, and finances. Other examples include frail seniors isolated from family and friends as they enter the health care system, or recently immigrated parents who must face a child's serious illness in the context of language and cultural barriers.

Within these diverse and challenging clinical and family contexts, nurses strive to provide *family-centred care*, an approach to care that is characterized by dignity and respect, information sharing, patient/family participation, and family-professional collaboration (Institute of Family Centred Care, n.d.). Despite the growing adoption of family-centred care within modern health care settings, implementation of this approach has been challenging. A lack of clarity in conceptual definitions and limitations in the availability of evidence-based practice models have posed significant challenges to the implementation of family-centred care (Franck & Callery, 2004). Wright and Leahey (2009) suggested that family-centred care can be responsibly and respectfully achieved only through the use of clearly articulated relational, family assessment, and family intervention frameworks.

Family nursing is based on the assumption that every person, regardless of age, is a member of some type of family form and carries family experiences that have profound influences on their lives and approaches to health care (Hartrick Doane & Varcoe, 2005). Also central is the assumption that individuals are best understood within the context of the family. A change in one family member, such as an illness or health condition, affects the other family members. Family nursing promotes, supports, and provides for the well-being and health of the family and individual family members (Wright & Leahey, 2009). Nurses need to understand the relational contexts as well as the particular strengths and needs of each family that they encounter in practice. It is also important that nurses work to understand the geo-social, economic, and political influences that shape each family's life experience. Through skilled relational inquiry (Hartrick Doane & Varcoe, 2005) and the use of family assessment and intervention frameworks, nurses can effectively collaborate with families to enhance the unique strengths and resources they possess (Hartrick Doane & Varcoe, 2005; Wright & Leahey, 2009). Nurses are encouraged to move beyond understanding family as an entity and into the sensitive mediation of the nurse-family relationship as well as the relationships shared between family members. The goal of family nursing is to help the family and its individual members achieve and maintain optimal health throughout and beyond the illness experience.

What Is a Family?

Defining *family* within complex relational and clinical contexts is not a simple undertaking. Different definitions have resulted in heated debates among social scientists and legislators. Formal definitions have included understandings of family as a biological or legal entity and social networks complete with personally or institutionally organized values and ideologies. To some patients, family may include only people who are related by marriage, birth, or adoption.

Other patients consider aunts, uncles, close friends, cohabiting people, and even pets as family. Families are as diverse as

the individuals that compose them, and patients, as well as health care providers, hold deeply ingrained beliefs and values about family. It is important that nurses explore these values and beliefs within their nursing practice with families. Thus, **family** is defined as a set of relationships that each patient identifies as family or as a network of individuals who influence each other's lives, regardless of whether actual biological or legal ties exist. In other words, each person has an individual definition of who or what constitutes family (Baumann, 2006).

Your personal beliefs do not have to coincide with those of the patient, but to provide responsive, individualized, and compassionate care, it is important to have an awareness of your own history, values, and beliefs and an understanding that families are diverse in form and expression. Families are unique, each having its own strengths, resources, and challenges (Bell et al., 2001; Hartrick Doane & Varcoe, 2005; Wright & Bell, 2009; Wright & Leahey, 2009). However, some general characteristics of a family include future obligations and caregiving functions, such as protection, nourishment, and socialization of its members (McGoldrick et al., 2011).

Current Trends in the Canadian Family

Although the institution of the family remains strong, the family itself is changing. You should be aware of current trends and social factors that affect the structure and function of the family. The following information about current family trends is based on data from Statistics Canada's 2006 censuses (Statistics Canada, 2012).

Family Forms

Family forms are patterns of people considered by family members to be included in the family (Box 19-1). Although all families have some common characteristics, each family form has unique challenges and strengths. You are encouraged to maintain an open mind about what constitutes a family so that potential resources and concerns are not overlooked.

Divorce rates have increased dramatically since the 1950s, and although the rate seems to be dropping, it is now estimated that 41% of Canadian marriages will end in divorce (Statistics Canada, 2012). Many divorced adults eventually remarry or form new family units, which results in blended families with complex sets of relationships among step-parents, stepchildren, half-brothers and half-sisters, and extended family members. When transitioning to a blended family, parents undergo difficult emotional challenges, while simultaneously managing the intense sadness, anger, and confusion experienced by children, extended family members, friends, and ex-spouses. Divorced and re-coupled families require an entirely new paradigm as they move forward in family life (McGoldrick et al., 2011).

For many years, lesbian, gay, bisexual, and transgender individuals have participated in family through their membership in families of origin, as well as in the families they have chosen to create both within and outside the context of legal marriage (McGoldrick et al., 2011). These individuals and couples face multiple challenges within the family life cycle, including those associated with identity development, the process of coming out, coupling, parenting, and transitions in later life. For more information, see *The Expanded Family Life-cycle: Individual, Family, and Social Perspectives* (McGoldrick et al., 2011, pp. 115-132).

► BOX 19-1 Family Forms

Traditional Nuclear Family

Consists of a mother and father (married or common-law) and their children

Extended Family

Includes the nuclear family and other relatives (perhaps grandparents, aunts, uncles, cousins)

Step-Family

Formed when at least one child in a household is from a previous relationship of one of the parents

Blended Family

Formed when both parents bring children from previous relationships into a new, joint living situation or when children from the current union and children from previous unions are living together

Lone-Parent Family

Consists of one parent and one or more children. The lone-parent family is formed when one parent leaves the nuclear family because of death, divorce, or desertion or when a single person decides to have or adopt a child.

Other Family Forms

Family forms and family relationships within Canada have become increasingly diverse. They include married and common-law couples without children, families in which grandparents provide care for their grandchildren, adults living alone, and same-sex couples (with or without children). The rates of traditional families (two married parents and children living together) in Canada is declining, while the proportion of common-law and single-parent families is increasing. Single-parent families accounted for 25.8% of Canadian families in 2006 (Statistics Canada, 2006).

Grandparents have increasingly taken responsibility for the raising of grandchildren. In 2011, about 0.5% of all grandparents were living with their grandchildren without either of the children's parents involved (Statistics Canada, 2012). This parenting responsibility is often a consequence of legal intervention when parents are deemed unfit or renounce their parental obligations.

Family Changes and Challenges: Understanding the Influence of Sociocultural Contexts

Sociocultural and economic changes are significantly increasing challenges to family health. Many families find themselves unable to respond effectively to complex family challenges (e.g., violence, addictions, illness, learning disabilities, cognitive decline and/or dementia). These family challenges can undermine existing relationships of care, leaving family members more vulnerable and socially isolated during times when support is most needed (Luxton, 2011). Recognizing these changes and challenges is crucial within family nursing assessment and intervention.

Teenage Pregnancy

The rate of teenage pregnancies in Canada has dropped dramatically, having decreased 36% between 1996 and 2006 (Canadian Federation for Sexual Health, 2007; McCay & Barrett, 2010). Nevertheless, adolescents who give birth are now more likely to raise their children as single parents or

within the context of extended family units rather than placing their children for adoption (Canadian Federation for Sexual Health, 2007). A teenage pregnancy often has significant health and social consequences for children and mothers and can severely strain family relationships and family resources. In addition, these families are at increased risk for living in poverty related to disruptions in maternal education and limited career opportunities.

Domestic Roles

Domestic roles have become more complex as families are increasingly made up of two wage earners or living in single person households (Statistics Canada, 2012). Balancing employment and domestic responsibilities creates a variety of challenges with regard to child and elder care, as well as household work. Concerns that maternal employment is detrimental to children's development and well-being are limited and unsubstantiated (Brooks-Gunn et al., 2010). However, finding high-quality child care and managing domestic tasks can be a major challenge. Management of domestic tasks and parenting responsibilities varies substantially from family to family. Many fathers are now expected and want to participate more fully in day-to-day parenting responsibilities. Additionally, cultural groups such as Aboriginal, European, African, Asian, and South Asian communities have historically valued and maintain extended family involvement in family caregiving (Luxton, 2011) (see Chapter 9).

Economic Status

In 2011 the median annual income of Canadian families was about \$76,600. The median annual income for lone-parent households was \$46,800 (Statistics Canada, 2012). Distribution of wealth greatly affects the capacity to maintain health. Low educational preparation, poverty, and decreased amounts of support all magnify the impact of illness on the family and increase the amount of illness in the family.

Aboriginal Families

Individual, family, and community impacts of social and health inequities and disparities in Canadian society are profound (Adelson, 2005) and require nursing attention. Aboriginal families are the fastest-growing group with children younger than 24 years. They are undergoing substantial changes while trying to maintain traditional culture, structure, and function. Aboriginal families, in their multigenerational form, often consist of a network of grandparents, parents, children, aunts, uncles, and cousins. Each member has obligations to the family. Children are held in high esteem and are expected to be treated gently and protected from harm (Castellano, 2002). Aboriginal families tend to be larger and younger and contain more diverse family members than non-Aboriginal families. Each group of Aboriginal peoples has its own traditions, rituals, relationships, and functions that need to be taken into account in nursing care. The Calgary Family Assessment and Intervention Models (Wright & Leahey, 2009), as well as Hartrick Doane and Varcoe's (2005) approach to family nursing as relational inquiry can assist nurses in creating a sensitivity and attentiveness to both the strengths and challenges faced by the Aboriginal families they encounter in practice.

Family Caregivers

Those 80 years of age and older are Canada's fastest-growing age group. One out of every seven Canadians is a senior

citizen. Life expectancy is 82.5 years for women and 77.7 years for men (Statistics Canada, 2012). The aging population has affected the family life cycle, especially the middle generation, as many family members serve as informal caregivers for older adults and other persons with disabilities. The majority of these caregivers are women, and they frequently provide 10 hours or more of unpaid assistance per week (Duxbury et al., 2009). Family caregiving involves the routine provision of services and personal-care activities for a family member by spouses, siblings, or children. Caregiving activities include personal care (bathing, feeding, or grooming), monitoring for complications or side effects of medications, instrumental activities of daily living (shopping or housekeeping), and ongoing emotional support. The respite needs of family caregivers are an important aspect of assessment and intervention given the changes occurring within the sociocultural and economic contexts of family health.

Although family caregivers often find that providing care has many rewards, this group frequently must balance caring for a family member with many other ongoing demands (e.g., raising children, working full-time, or dealing with personal problems or illness) and may suffer physical and emotional health challenges related to the competing demands (Duxbury et al., 2009). Box 19-2 provides a list of family nursing gerontological concerns.

The Family and Health

The family is the primary context in which health promotion and disease prevention take place (Box 19-3). The health of the family is influenced by many factors such as biology, social status, economic resources, politics, violence, and geographical and environmental contexts. Each family's beliefs, values, and practices also strongly influence the health-promoting behaviours of its members (Hartrick Doane & Varcoe, 2005, 2006). The health status of each individual influences how the family unit functions and its ability to achieve its goals. When the family meets its goals, its members tend to feel positive about themselves and their family. Conversely, when they do not meet goals, families may view themselves as ineffective.

* BOX 19-2 FOCUS ON OLDER ADULTS

- Nurses need to carefully consider caregiver strain; caregivers are typically older adults whose own physical stamina may be declining, or middle-age children who often have other responsibilities.
- Older families have a different social network than younger families; friends and same-generation family members may have died or have been ill themselves. Nurses can look for social support within the community and within the patient's religious affiliation.
- Physical health impairments increase the risk of depression in older adults.
- As in the other stages of life, members of older families need to work on developmental tasks (see Chapter 24).
- Abuse of older adults occurs across all social classes, with family members and family caregivers the most frequent abusers (Ford-Gilboe et al., 2011). Unexplained bruises and skin trauma should not be ignored by health care providers.

Attributes of Healthy Families

Researchers have focused on hardiness and resiliency as mediating factors for long-term health. Hill's (1958, 2003) classic research attempted to explain the reactions of crisis-proof and crisis-prone families in order to foster strength. A crisis-proof, or effective, family can integrate the need for stability with the need for growth and change. This type of family has a flexible structure for task performances and is receptive to help from outside the family system while maintaining a sense of strength and stability. An effective family exerts influence on the immediate environment of home, neighbourhood, and school, whereas a crisis-prone family may lack, or believe it lacks, control over these environments.

Family **hardiness** has been defined as the internal strengths and durability of the family unit and is characterized by a sense of control over the outcome of life, perceiving change as beneficial and growth producing, and active rather than passive approaches to stressful events (McCubbin et al., 1996). A hardy family can thus transcend inevitable lifestyle changes. Family **resiliency** is the ability to cope with expected and unexpected stressors: role changes, developmental milestones, and crises. The goal of the family is not only to survive the challenge but also to thrive and grow with knowledge acquired in the challenge.

Black and Lobo (2008) defined *family resiliency* as successful coping under conditions of stress and adversity that enables individuals and the family unit to flourish with support. Factors influencing family resiliency include positive outlook; spirituality; flexibility; cohesiveness; clear communication; financial management; shared family involvement in recreation, routines, and rituals; and support networks. Communication is particularly crucial to resilience and general family functioning. It enables individuals within a family unit to express needs, wants, and concerns to one another. Through communication, family members are able to resolve everyday challenges, promote health of all members, and develop resilience for extraordinary challenges (Black & Lobo, 2008; Svavarsdottir et al., 2000).

Health promotion programs, psychosocial supports, and family counselling or therapy aimed at enhancing communication and other resiliency attributes are available for families and children in many communities. Nurses need to make themselves aware of family-oriented community resources so that families can be referred as needed.

* BOX 19-3 FOCUS ON PRIMARY HEALTH CARE

Family nursing practice focuses on the active collaboration with individual members and the family unit with the goal of supporting their efforts to reach optimal levels of health and well-being. Community health nurses meet families in a wide variety of primary health care settings and have many opportunities to implement holistic family nursing practices. Nursing practices in health promotion include but are not limited to neonatal assessments, bereavement visits, school health care, occupational health care, substance abuse programs, palliative care, infusion clinics, and home care. Research has shown that these nursing interventions have a positive impact on the health outcomes of families (MacMillan et al., 2009).

Family Nursing Care

A collaborative relationship with family members must be based on mutual respect and trust. Nurses should examine family patterns, relationships, and interactions when they consider how a health challenge or illness affects a family and how a family affects a health challenge or illness (Leahey & Harper-Jaques, 1996). A nurse's relationship with the family has a significant influence on patient/family functioning and health outcomes (Leahey & Harper-Jaques, 1996; MacMillan et al., 2009) (Figure 19-1).

Although health care systems in the past tended to emphasize the individual, a family focus is now needed in order to be able to safely discharge patients to the care of the family or community settings. There is also a pressing need to address the challenges faced by multiple family members, the patient, and the family unit within nursing practice. To begin working with families, you must have scientific knowledge of family theory and family nursing. Family nursing care focuses on family as context, family as patient, and an understanding of families *in* context. The approaches used depend on the particular situation and the self-awareness and abilities of the nurse.

Family as Context

When considering the family as **context**, you focus either on the individual patient within the context of his or her family, or on the family with the individual as context (RNAO, 2006). The approach used relates to the clinical setting, clinical problem, and practical considerations. An example of the first approach is a situation in which a nurse interviews a man with heart disease, asking the man's wife about the family's diet and possible family stressors. The wife's ability to support her husband's efforts at changing eating patterns and use of stress management techniques are also assessed. The main focus is on the health of the patient within the environment of the family. An example of the second approach is a situation in which a community health nurse interviews the adult daughter of a woman with multiple sclerosis, discussing how she is coping with her mother's care. Family members may need direct support and nursing intervention themselves.

With both approaches, you assess the extent to which the family supports the individual's basic needs. Family members are considered valuable resources for assessment

and intervention. They provide information about how they have been helping the patient maintain health and manage health problems. When patients are unable to communicate, families provide important information about the patient and indicate the patient's wishes. Nurses need to be competent at considering the family as context. Even if there is no opportunity to involve the family directly, you still consider the patient as a member of a family.

Family as Patient

When approaching the family as patient, you focus on the entire family: its processes and relationships (e.g., parenting, impacts of the marital relationship, or family caregiving). Family patterns and interactions among family members are the focus, rather than individual characteristics. The nursing process concentrates on how these patterns and processes are consistent with achieving and maintaining family and individual health. Nursing practice that focuses on family as patient is also known as *Family Systems Nursing* and requires in-depth knowledge of family dynamics and family systems theory (Wright & Leahey, 2009). Therefore, nurses who specialize in Family Systems Nursing often have advanced skills and training. An interdisciplinary approach is helpful when dealing with complex family systems. It is important that you are aware of the limits of nursing practice and make referrals when appropriate. Considering the family as the patient, you aim to support communication and healthy family functioning among family members (Wright & Leahey, 2009). Often you must support conflict resolution between family members so that each member can confront and resolve challenges in a healthy way. You also may link family members to external and internal resources as necessary. Ultimately, your aim is to help the family achieve optimal functioning.

Understanding Family in Context: Family Nursing as Relational Inquiry

Family nursing as relational inquiry invites nurses to consider the ways in which families and nurses are embedded within diverse and complex life contexts. Hartrick Doane and Varcoe (2005) articulated the importance of critically attending to the social, political, economic, and geographical contexts that influence both family members and nurses who care for them. Nurses need to continually explore how personal and professional definitions of *health* and *family* may shape, and possibly constrain, their nursing practice with families (p. 24). A nurse's perceptions, values, and beliefs about the meaning of family can greatly influence the quality of the therapeutic relationship, the health of patients and families, and the quality of work life experienced by nurses. A **relational inquiry** approach asks nurses to expand their contextual knowledge of families, developing a more in-depth and comprehensive consideration of the historical, economic, political, social, environmental, and geographical influences at play when families encounter illness or other difficulties related to life transitions.

The nurse's awareness of his or her own values and beliefs as well as a critical, reflective consideration of different understandings of health and family will enhance the nurse's ability to hear the unique stories of family members' lives. Nurses must explore potential biases they may hold, how those biases may influence the questions they ask, and their ability or inability to listen for and to the experiences of family members.

This practice is guided by a number of relational capacities that have been described by Hartrick Doane and Varcoe (2005).

Figure 19-1 Nurse (left) and family members.

► BOX 19-4 Relational Capacities

Key concepts of relational practice with families:

- Self-awareness (in relationship with others)
 - Context/Culture
 - Perception/Personal Meaning
 - Relational Capacity (approaches identified in detail below)
- Relational capacities:
- Ways of being in relationship
 - Presencing/mindfulness
 - Synchrony/mutuality
 - Capacity for ambiguity
 - Intentionality/congruence
 - Genuineness
 - Warmth
 - Respect
 - Attending/listening (including listening for difference)
 - Boundaries
 - Understanding another's personal meaning
 - Empathy
 - Clarification/perception checking/verbalizing the implied
 - Validating
 - Question posing, focusing, and reflecting
 - Use of silence
 - Summarizing/placing events in a time sequence
 - Expressing/sharing your own personal meaning
 - Constructive giving/receiving of feedback
 - Assertiveness
 - Conflict resolution
 - Sharing information

Source: Adapted from Hartrick Doane, G., & Varcoe, C. (2005). *Family nursing as relational inquiry: Developing health promoting practice* (p. 288; Box 7.1). Philadelphia, PA: Lippincott Williams & Wilkins.

These skills include listening, questioning, empathy, mutuality, reciprocity, self-observation, reflection, and a sensitivity to emotional contexts (also see Chapter 17). This approach highlights working across differences and acknowledging that power and differences are important, often invisible, features of relationships. This practice begins by entering into relation, enquiring into the family health and healing experience, following the lead of families, and learning to let be (see Box 19-4). Within your own practice, consider how you might look beyond the surface of patients and families, entering your practice with an approach of inquiry, while drawing on the assessment and intervention processes described in Box 19-5.

Assessing the Challenges, Strengths, and Needs of the Family: The Calgary Family Assessment Model

Family assessment skills are also essential in providing responsive, compassionate, and respectful family care and support. To help families adjust to acute and chronic illness, nurses need to understand the relationships that family members share, what the illness means to family members, how the illness has influenced family functioning, how the family has been affected by the illness, and the support that the family is most in need of (Neabel et al., 2000; Wright & Leahey, 2009). Box 19-6 lists the particular features of families who should be considered for a

► BOX 19-5 Relational Inquiry: Assessing and Intervening Approaches

1. Entering Into Relation: Getting "in Sync" With a Family

- Conscious participation—Walking alongside the family
- Stopping to look, listen, and hear
- Unconditional positive regard
- Being in sync

2. Being in Collaborative Relation: Staying "in Sync"

- Family and nurse working together to assess and intervene

3. Inquiring Into the Family Health and Healing Experience

- Inquiry into what is meaningful to the family
- Keeping family at the centre of view

4. Following the Lead of Families

- Taking cues from families
- Taking a stance of curiosity, unknowing, and uncertainty
- Using theoretical knowledge to enhance sensitivity to family experience
- Scrutinizing theoretical and expert knowledge against family experience

5. Listening to and for

- Listening through phenomenological, critical, spiritual, and socioenvironmental health-promotion lenses

6. Self-Observation

- Participating consciously and intentionally
- Self-knowing

7. Letting Be and Change

- Letting be to know who this family is and what is happening for them
- Creating the opportunity for family to come to know more about their own experience, patterns, capacities, challenges, and contextual constraints

8. Collaborative Knowledge Development

- Drawing on family knowledge (experiential, historical, sociocultural), and drawing on nursing knowledge (scientific, theoretical, biomedical, political, practical)

9. Pattern Recognition

- Identifying underlying patterns of experience and responses
- Identifying patterns of capacity and capacity-adversity

10. Naming and Supporting Capacity

- Seeing and recognizing strengths
- Looking beyond the surface
- Honouring the family's version of the story
- Working with the family to enhance capacity and address adversity

11. Emancipatory Action

- Recognizing and naming inequities and structural conditions
- Drawing on and sharing contextual knowledge
- Introducing alternative discourses
- Devoting energy to remedying structural inequities and creating coalitions

Source: Adapted from Hartrick Doane, G., & Varcoe, C. (2005). *Family nursing as relational inquiry: Developing health promoting practice* (p. 288; Box 7.1). Philadelphia, PA: Lippincott Williams & Wilkins.

family assessment. During an assessment, the nurse, patient, and family engage relationally and collaboratively in conversation to share information with each other and explore family members' experiences of illness, while simultaneously reflecting on issues important to the patient and family's well-being.

► BOX 19-6

Features of Families Who Should Be Considered for a Family Assessment

Families who may benefit most from a family assessment include those who

- Are experiencing emotional, physical, or spiritual suffering or disruption caused by a family crisis (e.g., acute, chronic, or life-threatening, illness, injury, death, addiction, and/or suspected family violence)
- Are experiencing emotional, physical, or spiritual suffering or disruption caused by a developmental milestone (e.g., birth, marriage, child leaving home)
- Define a problem or illness as a family issue (e.g., the impact of chronic illness on the family)
- Have a child or adolescent whom they identify as having difficulties (e.g., bullying at school, fear of cancer treatment)
- Are experiencing issues that are serious enough to jeopardize family relationships (e.g., terminal illness, abuse, addictions)
- Have a family member who is about to be admitted to the hospital for psychiatric or mental health care
- Have a child admitted to the hospital

Source: Adapted from Wright, L. M., & Leahey, M. (2009). *Nurses and families: A guide to family assessment and intervention* (5th ed., p. 5). Philadelphia, PA: F. A. Davis Company.

The **Calgary Family Assessment Model (CFAM)** is a relational, strengths-focused practice model that guides nurses in the completion of comprehensive family assessment (Wright & Leahey, 2009). The CFAM has received international recognition and has been adopted by schools of nursing around the world. The CFAM focuses on three major categories of family life: structural, developmental, and functional dimensions. Each category has several subcategories; however, not all subcategories will be relevant to every family (Figure 19-2). Nurses must decide, on a family-by-family basis, which subcategories are most relevant. Using too many subcategories may result in an overwhelming amount of data and questions for family members; using too few may yield insufficient data, which can distort a family's strengths and/or challenges. The model can be consulted during discussions about family issues.

Structural Assessment

The structural dimension of the family assessment includes:

- **Internal structure:** the people who are included in the family and how they are relationally connected to one another
- **External structure:** the relationships the family shares with people and institutions outside of the family unit
- **Context:** the whole situation or background relevant to the family

Internal Structure. The internal structure of the family—the composition and relationships shared by family members—can be further divided into six subcategories: family composition, gender, sexual orientation, rank order, subsystems, and boundaries.

Family Composition. *Family composition* refers to the individual members who form the family. The family

Figure 19-2 Branching diagram of the Calgary Family Assessment Model (CFAM). **Source:** Wright, L. M., & Leahey, M. (2009). *Nurses and families: A guide to family assessment and intervention* (5th ed., p. 48, Fig. 3-1). Philadelphia, PA: F. A. Davis.

composition is not limited to the traditional, nuclear family; it may include any of the various family forms, which were previously discussed (see Box 19-1). It is important to note whether any recent additions or losses in the family composition have occurred.

Questions to Ask the Family

- Who is in your family?
- Does anyone else live with you: for example, grandparents, boarders?
- Has anyone recently moved out of your household, married, or died?
- Can you think of anyone else who is like a family member but is not biologically related?

Gender. *Gender* is the set of beliefs about or expectations of masculine and feminine behaviours and experiences. These beliefs are fundamental to intimate relationships and are influenced by culture, religion, and family. It is useful to understand how male and female members of a particular family may view and experience the world differently.

Questions to Ask the Family

- How have your parents' ideas about masculinity and femininity affected your own? Have your ideas about gender been challenged in any way since you became parents?
- Do you have expectations of your children on the basis of their gender?
- Is the division of labour at home based on gender roles?

Sexual Orientation. *Sexual orientation* refers to heterosexual, homosexual, bisexual, or transgendered orientation (see Chapter 26). Heterosexism, a belief that male–female bonding is the only legitimate type of bonding, is a form of bias that can affect families and health care providers. Discrimination based on sexual orientation remains a problem. Unless relevant to the patient or family's presenting concern, you do not usually ask questions about sexual orientation, but avoid stereotyping or making assumptions when you ask general questions.

Rank Order. The order of children by age and gender is called *rank order*. The birth order, gender, and distance in age between siblings are important considerations because they may influence roles and behaviours. The child's characteristics and the family's idealized "program" for the child (going to school, college, university, work, getting married, and so forth) are also important.

Questions to Ask the Family

- How many children are in your family?
- What are the children's ages?
- Do you have distinct expectations for the oldest and younger children?

Subsystems. *Subsystems* are smaller groups of relationships (i.e., based on generation, interests, skills, or gender) within a family. For example, a family could have a sibling subsystem, a husband–wife subsystem, and a parent–child subsystem. Each family member usually belongs to several subsystems, and in each subsystem, they play a different role, use different skills, and have a different level of power (i.e., a teenager behaves differently with her younger sister than she does with her father). Adapting to the demands of different subsystems is a necessary skill for each family member.

Questions to Ask the Family

- What groups have you noticed in your family?
- Are there times when disagreements occur among and between the subgroups in your family?

- If your family had more or fewer subgroups, what effect do you think that might have? What might you most like to change about the subgroups in your family?

Boundaries. Boundaries define family subsystems and distinguish one subsystem from another. They influence how members participate in each subsystem. For example, a child in a parent–child subsystem may be given certain responsibilities and power but is not expected to be involved with family decision making. Boundaries can be weak, rigid, or flexible, and they change over time as family members age or are gained or lost.

Questions to Ask the Family

- Whom do you talk with when you feel happy? Who do you talk to when you feel sad?
- Does the family have any "unwritten" rules about topics never to be discussed outside of the family?

External Structure. *External structure* refers to the connections that family members have to persons outside the family. Two subcategories of external structure exist: extended family and larger systems.

Extended Family. *Extended family* includes the family of origin, the current generation, and step-relatives. How each member sees himself or herself as an individual, yet also as part of the family, should be critically assessed. You should note whether family members make many references to the extended family during the interview and inquire about the nature of the relationships shared with extended family members.

Questions to Ask the Family

- Where do your parents live? How often do you have contact with them and your siblings?
- Which family members do you see or speak with regularly? Who in your extended family are you the closest to?
- Have members of your extended family been helpful to you during this time of illness? In what way?

Larger Systems. *Larger systems* are groups with whom the family has meaningful contact. Groups include health care organizations, work, religious affiliations, school, friends, and social agencies such as public welfare, child welfare, foster care, and courts. Usually, contact with such larger systems is helpful. However, some families have difficult relationships with individuals from these groups, which can create stress for the family.

Questions to Ask the Family

- How many health agencies regularly interact with you?
- What agency professionals are involved with your family? How have they been helpful or not helpful to your family? How are you hoping I might support you differently than other professionals involved in your family's care?

Context. *Context* refers to the situation or background relevant to the family. A family can be viewed in the context of ethnicity, race, social class, religion and spirituality, and environment.

Ethnicity. *Ethnicity*, which is the concept of a family's cultural, historical, geographic, linguistic, and ethnic heritage can greatly influence family interaction. Ethnicity may influence a family functioning, structure, perspectives, values, health beliefs, and philosophies (see Chapter 9). Cultural and ethnic heritage can affect, for example, religious practices, child-rearing practices, recreational activities, and nutrition. Individually focused assessment is important as different members of an ethnic group may subscribe to differing beliefs, traditions, and restrictions, even within the same generation.

Questions to Ask the Family

- Do you think of your family as having a strong ethnic identity?
- Has your ethnic background influenced your health care?
- Could you tell me about ethnic traditions you practise? How are these traditions helpful to your family?

Race. Race (biological characteristics such as skin and hair colour) influences individual and group identification and is closely connected to ethnicity. Family members' interactions among themselves and with health care providers are influenced by racial attitudes, stereotypes, and discrimination. If ignored, these influences may constrain the nurse and family's relationship.

Questions to Ask the Family

- If you and I were of the same race, would our conversation be different? How?

Social Class. Social class is shaped by education, income, and occupation. Each class has its own values, lifestyles, and behaviours that influence family interaction and health care practices.

Questions to Ask the Family

- What is your job? How many hours a week do you work? How does this affect family life?
- Does anyone in the family work shifts? How does that influence your family functioning?
- What level of education have you completed?
- Does your family have economic challenges at this time?

Religion and Spirituality. Family members' spiritual or religious beliefs, rituals, and practices can influence their ability to cope with or manage an illness or health concern (McLeod, 2003; McLeod & Wright, 2001, 2008; Walsh, 2010a, 2010b; Wright, 2005, 2008; Wright & Bell, 2009). Spirituality is often an underused resource in family nursing (see Chapter 27). Increasingly, families choose to explore the spiritual beliefs and practices that best fit their multifaceted lives, beliefs about spirituality, and relationships. Spiritual assessment and support will therefore be highly individualized within an inquiry-oriented approach (Hartrick Doane & Varcoe, 2006; Walsh, 2010a).

Questions to Ask the Family

- What spiritual practices does your family have? What priority do these practices hold in your family? Have your family's spiritual beliefs changed or been challenged in any way during this illness?
- Are you involved in a particular church, temple, mosque, synagogue, group, religious, or spiritual community?
- Would you discuss a family problem with anyone from your place of worship?
- Do you consider your spiritual beliefs a resource? A source of stress?

Environment. The family *environment* refers to the larger community, neighbourhood, and home. Environmental factors that may affect family functioning include availability or lack of adequate space and of access to schools, day care, recreation, and public transportation.

Questions to Ask the Family

- What are the advantages and disadvantages of living in your neighbourhood?
- What community services does your family use?
- What community services would you like to learn about?

Structural Assessment Tools. The CFAM encourages you to work with family members to create genograms and ecomaps to facilitate documentation and understanding

Figure 19-3 Sample family genogram. **Source:** Adapted from Wright, L. M., & Leahey, M. (2009). *Nurses and families: A guide to family assessment and intervention* (5th ed., p. 75, Figure 3-4). Philadelphia, PA: F. A. Davis.

of the family structure and its contact with outside individuals and organizations. A **genogram** is a sketch of the family structure and relevant information about family members (Figure 19-3). Some agencies have genogram forms, but genograms can also be sketched on other forms, such as admission forms and records. The genogram becomes part of the documentation about the patient and family. An **ecomap** is a sketch of the family's relationships with persons and groups outside the family (Figure 19-4). The family members who share the household are depicted in the centre of the ecomap, and various important extended family members or larger systems are sketched in to show their relationship to the family.

Nurses are encouraged to draw genograms and ecomaps for families with whom they will be involved for more than one day. Information for brief genograms and ecomaps can be gleaned from family members during the initial assessment of the family structure. The most essential information for genograms includes data about ages, occupation or schooling, religion, ethnicity, and current health status of family members. For a brief genogram, focus only on information relevant to the family and the health problem. The shared creation of a genogram by a nurse and family can be an important time for the nurse to engage with the family, forming a relational connection between family members and the nurse. Engagement can be facilitated through the use of humour, curiosity, and invitations for family members to describe the strengths they see in one another. For example, the nurse might ask a child (eight years old), "What do you most like about your dad?"

Figure 19-4 A sample family ecomap. RN, registered nurse. **Source:** Adapted from Wright, L. M., & Leahey, M. (2009). *Nurses and families: A guide to family assessment and intervention* (5th ed., p. 84, Figure 3-10). Philadelphia, PA: F. A. Davis.

Developmental Assessment

Families, like individuals, change and grow over time. Although each family is unique, all families tend to go through certain stages that require family members to adjust, adapt, and change roles. Each developmental stage presents challenges and includes tasks that need to be completed before the family can successfully move on to the next stage. Family development is more than the concurrent development of children and adults. It is the interaction between an individual's development and the phase of the family developmental life cycle that can be significant for family functioning. Therefore, in addition to understanding family structure, nurses need to understand the developmental life cycle of each family.

In their articulation of the expanded family life cycle, McGoldrick and colleagues (2011) described the emotional process of life cycle transition, as well as the family development tasks for different stages. The family life cycle stages described include: "Leaving Home: Emerging Young Adults, Joining of Families Through Marriage Union, Families with Young Children, Families with Adolescents, Launching Children and Moving on at Midlife, Families in Late Middle Age, and Families Nearing the End of Life" (pp. 16-17). Additionally, the unique challenges faced by single parent, lesbian, gay, bisexual, and transgender families, as well as those facing transitions related to divorce, are discussed. Understanding family development theory can help nurses to promote health during expected family life cycle transitions and experiences of illness. For further information, please see *The Expanded Family Life Cycle: Individual, Family, and Social Perspectives* (4th edition) (McGoldrick et al. (2011).

Functional Assessment

A *functional assessment* focuses on how family members interact and behave toward each other. Nurses assess family

functioning by closely observing the interactions of family members in two subcategories: instrumental and expressive functioning.

Instrumental Functioning. *Instrumental functioning* refers to the normal activities of daily living such as preparing meals, eating, sleeping, and attending to health needs. For families with health problems, these activities often become a challenge. Roles may change as family members cope with a relative's illness and disability. Within the context of illness, nurses and other health care providers play an important role in accessing practical and financial resources to support family members' instrumental needs (i.e., financial resources for medical supplies that parents need to care for an ill child at home).

Questions to Ask the Family

- Who is usually responsible for housekeeping and child care?
- Do other family members help with these tasks?
- Does anyone in the family require help with activities of daily living?
- Who will be primarily responsible for flushing Mary's broviac line (an intravenous access device for the administration of medications and blood tests) when she is discharged home?

Expressive Functioning. *Expressive functioning* refers to the ways in which people communicate. The significance of communication within the family cannot be emphasized enough, for it has a profound impact on a family's adjustment to illness, and their resiliency in the face of developmental and illness related challenges. Illness and disability often challenge and alter expressive functioning within the family. A diagnosis may cause intense feelings of anxiety or grief, both within the person being diagnosed and within other family members. Nurses should encourage families to explore their

understanding of illness and how it affects their lives. Nurses may need to assist family with these difficult conversations, given the emotional intensity of this communication (Box 19-7). There are ten subcategories of expressive functioning: emotional, verbal, nonverbal, and circular communication; problem solving; roles; influence; beliefs; and alliances and coalitions.

Emotional Communication. Emotional communication encompasses the range and types of feelings that are expressed by the family. Most families express a wide range of feelings. Families with problems may have rigid patterns and narrower ranges of emotional expression (e.g., a family coping with a father's cancer diagnosis may be anxious and unable to express optimism or hope for the future). Family roles and gender may affect emotional expression. For example, brothers and sisters who have a sibling with a life-threatening illness may not express their own experiences of suffering because they want to protect their family from further distress and worry (Woodgate, 2006).

Questions to Ask the Family

- How can you tell when each member of your family is happy, sad, or under stress?
- How do you express happiness, sadness, or stress?
- Johnny, when you are sad or worried, who in the family do you most like to spend time with or talk to about that?

Verbal Communication. Nurses should observe a family's verbal communication, focusing on the meaning of the words in terms of the relationship. Is communication among family members clear and direct, or is it vague and indirect? Ask family members about how well the family communicates

Questions to Ask the Family

- Which family member communicates most clearly?
- How might your family members communicate with each other more effectively?
- Families sometimes find it helpful to talk with one of the nurses about their life at home after learning about the illness. Do you think your family would find that helpful?

Nonverbal Communication. Nonverbal communication consists of messages conveyed without words, including body language, eye contact, gesturing, crying, and tone of voice.

Questions to Ask the Family

- How do you think your daughter feels when your son rolls his eyes while she's talking?
- Who shows the most distress when talking about your dad's drinking? What are some of the nonverbal signals that indicate your daughter is distressed when talking about her dad's drinking?

Circular Communication. Circular communication refers to reciprocal communication between family members; that is, each person influences the behaviour of the other. Circular communication can be adaptive or maladaptive. For example, an adaptive communication pattern occurs when a parent comforts a child when the child cries. Because the parent responds to the child, the child feels safe and secure. An example of a maladaptive communication pattern is when a parent criticizes a teenager for not phoning home. The teenager is angry for being criticized and avoids the parent, and then the parent becomes angrier and criticizes more.

Questions to Ask the Family

- You mentioned that your teenager does not phone home. What do you do then?
- What do you think your daughter is thinking when you criticize her?

BOX 19-7 RESEARCH HIGHLIGHT

Research Focus: Therapeutic Conversations With Family Members Experiencing Childhood Cancer

Research Abstract

Children with cancer and their families experience physical, emotional, spiritual, and relational illness distress. Families have described the sadness and fear they live with and the difficulty experienced in talking about cancer. Despite calls for comprehensive psychosocial intervention, childhood cancer research that examines family intervention has been limited. West (2011) recently conducted a qualitative study that analyzed videotaped therapeutic conversations from the Family Nursing Unit, University of Calgary, as well as research interviews with family members (19) and nurse clinicians (3) following their participation in a Family Systems Nursing clinical intervention. The therapeutic conversations were guided by the Illness Beliefs Model (Wright & Bell, 2009). The research questions explored the internalized questions that parents, ill children, brothers, and sisters ask themselves while living with childhood cancer, and how nurses could better attend to their suffering. The research approach used was philosophical hermeneutics (Gadamer, 1989). Nursing interventions that were found to lessen illness suffering included bringing the family and nurse together for the purpose of a therapeutic conversation and creating a therapeutic space where illness suffering was brought forward through the sharing of illness experiences with the nurse, as well as other family members. West (2011) found that when nurses invited family members into a reflective, listening stance, they were assisted to hear each other's illness experiences, which facilitated new interpretations of their suffering. Integral to this intervention process was the nurse's presence, described as a "holding" or "containing" of suffering, giving family members the experience of being heard, and opening families to new interpretations of their suffering through the offering of alternative illness beliefs. Questions and nursing responses that invited family members to externalize their internalized questions and dialogue were particularly helpful in lessening suffering. Sharing commendations with family members was also another valuable nursing intervention that helped to enhance family strengths and lessen experiences of suffering.

An interview excerpt with Lizzie (14-year-old sister, research participant) highlights the profound importance of family nursing practices:

Lizzie: Well see, when you're in the hospital with your children for six months, a year, or for the rest of their life, you get disconnected from all your other children. So if you have an opportunity to sit down with the whole family . . . with your children, and talk to someone about what's going on, and just open up and share . . . you should take it cause it would really show . . . what everyone is going through. Because even though you're at the hospital, your children at school or the house . . . you don't know what's happening. Like, at times, I cried myself to sleep at night and I could hear Jason [brother] in the other room and . . . there's just so much that goes on, that no one really knows. Like even my sister Rachael, even though she was always home, or we were gone, and we would come home . . . her eyes would just be bright red from crying, and you could see the tear going down her . . . so take a chance, or the opportunity to sit down with the whole family and talk. It would really help (Research Interview excerpted from West, 2011, p. 201).

Problem Solving. Problem solving refers to how a family thinks about actions to take to resolve difficult situations.

Questions to Ask the Family

- Who first notices problems? How does your family tend to deal with problems?
- Is one member more proactive than others about solving problems?

Roles. Roles are established patterns of behaviour for family members, often developed through interactions with others. Formal roles include those of mother, husband, friend, and so forth. Informal roles can include, for example, those of “the softy,” “the angel,” or “the scapegoat.” In the context of illness, family members often must take on new roles, such as medical caregiver.

Questions to Ask the Family

- Who is the “good listener” . . . who is “the angel” in your family?

Influence. Influence refers to methods of affecting or controlling another person’s behaviour. Influence may be instrumental (e.g., rewards for behaviour such as the promise of candy, computer time), psychological (communication to influence behaviour such as praise, admonishment), or corporal (the use of body contact such as hugging, hitting).

Questions to Ask the Family

- What method does your mom use to get you to go to bed on time?
- How does your grandma get your brother to attend school when he refuses?

Beliefs. Beliefs are individual- and family-held fundamental ideas, values, opinions, and assumptions (Wright et al., 1996). Understanding the core beliefs (Wright & Bell, 2009) of family members is central to understanding their suffering and to facilitating healing in the context of illness (Wright et al., 1996; Wright & Bell, 2009). Beliefs influence behaviour and how the family adapts to illness. For example, if a family believes that vaccinations may cause disabilities, the parents may decline vaccinating an infant.

Questions to Ask the Family

- What do you believe causes your husband’s depression?
- What do you believe would be the effect on your chronic pain if you chose to participate in that treatment?

Alliances and Coalitions. Alliances and coalitions involve the directionality, balance, and intensity of relationships among family members or between families and nurses.

Questions to Ask the Family

- If the children are playing well together, who would be most likely to get them to start fighting?
- Is there anything that you were hoping we would talk about today that we haven’t spoken about?

Family Intervention: The Calgary Family Intervention Model

After assessment, nurses intervene to help families meet their needs, face challenges, and appreciate their strengths. A range of family nursing interventions can be offered to families in the context of a therapeutic relationship. Some, such as parent education and caregiver support, are general; others are specific and require therapeutic communication and family interviewing skills. The ultimate goal is to help family members discover alternative solutions that may lessen or alleviate emotional, physical, and spiritual suffering. Whether caring for a patient with the family as context or directing care to the

family as patient, nursing interventions aim to enhance family members’ abilities in certain areas, to remove barriers to health care, and to perform actions that the family cannot perform for itself. Nurses guide the family in problem solving, provide practical services, and convey a sense of acceptance and caring by listening carefully to family members’ experiences, concerns, suggestions, and questions.

Interventions for each family must be individualized and focus on particular areas of family functioning (cognitive, affective, behavioural) (Wright & Leahey, 2009). You can only *offer* interventions and must not instruct or insist on a particular kind of change or way of family functioning. Nurses need to sensitively attend to ideas or interventions the family perceives as being most helpful (Wright & Leahey, 2009).

The **Calgary Family Intervention Model (CFIM)** is a companion to the CFAM and can be used as a guide for your intervention with the family (Wright & Leahey, 2009). The CFIM focuses on promoting and improving family functioning in three domains: cognitive, affective, and behavioural. Interventions may affect functioning in any or all of the three domains. For example, when a clinic nurse informs a wife that her husband, who has amyotrophic lateral sclerosis, is still capable of large gross motor movement, the nurse can suggest he help with chores in the house, such as bringing the laundry upstairs. This intervention challenges the wife’s thinking that her husband was incapable of work, influences her to feel less depressed over her husband’s declining physical capacity, and leads her to change her behaviour by including her husband when performing other household chores.

The CFIM recommends many relational nursing practices that promote family health and functioning, including asking interventive questions, offering commendations, providing information, validating emotional responses, encouraging illness narratives, supporting family caregivers, and encouraging respite. Central to this interventional practice is the nurse’s engagement with family members in a thoughtful, purposeful relation (Tapp, 2001) (Table 19-1). Within CFAM and CFIM, as well as in the Illness Beliefs Model (Wright & Bell, 2009; Wright et al., 1996), nurses are guided to continually attend to the cultivation of a relationship that is collaborative, responsive, and nonhierarchical. Within this relationship, there is a privileging of family expertise and a commitment to listening deeply to the concerns, suffering, and questions of family members.

The guidance provided by Hartrick Doane and Varcoe (2005) in their discussion of family nursing as relational inquiry can also be a helpful guide for your relational engagement with the families you encounter in your practice.

Asking Interventive Questions

One of the most effective ways that nurses can help families is by engaging in therapeutic conversations with families and asking them questions. Questions lead the family to reflect on their situation, clarify opinions and ideas, and understand how they are affected by their family member’s illness or condition. By hearing their own responses to questions, as well as the responses of others, family members can better understand themselves and each other and perhaps discover new possibilities for health and healing. Interventive questions also elicit information important to the nurse.

There are two types of interventive questions: linear and circular (Tomm, 1987, 1988). **Linear questions** elicit information about a patient or family. They explore a family member’s descriptions or perceptions of an illness or life challenge. For

► **TABLE 19-1 The ABCs of Engaging Families**

A	B	C
Assume an active, confident approach.	Begin by providing structure to the meeting (time frame, orientation to the context).	Create a context of mutual trust.
Ask purposeful questions that draw forth family assessment data.	Behave in a curious manner, and take an equal interest in all family members, whether present or not.	Clarify expectations about your role with the family.
Address all who are present, including small children.	Build on family strengths by offering commendations to the family.	Collaborate in decision making, health promotion, and health management.
Adjust the conversation to children's developmental stages.	Bring relevant resources to the meeting (list of agencies, phone numbers, pamphlets).	Cultivate a context of racial and ethnic sensitivity. Commend family members.

Source: Adapted from Levac, A. M. C., Wright, L. M., & Leahey, M. (2002). Children and families: Models for assessment and intervention. In J. A. Fox (Ed.), *Primary health care of infants, children, and adolescents* (2nd ed.; p. 111). St Louis, MO: Mosby.

example, linear questions may be used when exploring a couple's perceptions of their daughter's anorexia nervosa: "When did you notice that your daughter had changed her eating habits?" "Has she been hospitalized in the past for this problem?" These questions inform you of the daughter's eating patterns and illuminate family perceptions or beliefs about eating patterns.

Circular questions help determine possible changes for a patient's or family's life. They help you understand relationships between individuals, beliefs, and events and elicit valuable information to help create change. In this way, circular questions often help patients make new cognitive connections, paving the way for changes in family behaviours. For example, with the same family, you could ask, "Who is most worried about Cheyenne's anorexia?" or "How does Ellen show that she's worrying the most?" Although linear questions may imply that you know what is best for the family, circular questions facilitate change by inviting the family to discover their own answers. Linear questions tend to target specific yes or no answers, thereby limiting options for the family; for example, "Have you tried time out to discipline your three-year-old?" An alternative circular question might be "Which type of discipline seems to work best for your child?" Several types of circular questions exist; each can affect the cognitive, affective, and behavioural domains. These types include difference questions, behavioural effect questions, hypothetical or future-oriented questions, and triadic questions (Tomm, 1987, 1988; Wright & Leahey, 2009) (Table 19-2).

Offering Commendations

Families do not always view themselves as having inherent strength and resilience. You can help the family become aware

► **TABLE 19-2 Three Types of Circular Questions**

EXAMPLES TO ELICIT CHANGE

Purpose of Question	Cognitive Domain	Affective Domain	Behavioural Domain
Difference Question			
Explores differences between people, relationships, time, ideas, or beliefs	What is the best advice given you about supporting your son with AIDS? What is the worst advice?	Who in the family is most worried about how AIDS is transmitted?	Which family member is best at getting your son to take his medication on time?
Behavioural Effect Question			
Explores connections between how one family member's behaviour affects other members	What do you know about the effect of life-threatening illness on children?	How does your son show that he is afraid of dying?	What could you do to show your son that you understand his fears?
Hypothetical/Future-Oriented Question			
Explores family options and alternative actions or meanings in the future	What do you think will happen if these skin grafts continue to be painful for Dan?	If Dan's skin grafts are not successful, what do you think his mood will be? Angry? Resigned?	When will your son engage in treatment for his contractures?
Triadic Question			
Question posed to a third person about the relationship between two other people	If your father were not drinking daily, what would your mother think about his receiving treatment for alcoholism?	What does your father do that makes your mother less anxious about his condition?	If your father were willing to talk to your mother about solutions to his addiction, what do you think he might say?

Source: Adapted from Wright, L. M., & Leahey, M. (2009). *Nurses and families: A guide to family assessment and intervention* (5th ed., pp. 162–163). Philadelphia, PA: F. A. Davis.

of their unique strengths, thus increasing their potential and capabilities. A **commendation** is a conversational statement emphasizing family strengths and abilities. While spending time with the family, you may observe many instances in which the family displays strengths. It is important to acknowledge these with the family so that they can recognize and appreciate their capabilities. By commending a family's strengths and capacities, you can offer family members a new view of themselves, and this may invite a change in how they view their health challenges. Look for patterns of behaviour to commend, rather than a single occurrence. For example, you may say, "Your family has shown courage living with your wife's cancer for five years" or "I'm impressed with how the family worked together during the crisis." Families coping with chronic, life-threatening, or psychosocial problems frequently feel hopeless in their efforts to overcome or live with the illness. Therefore, you should offer as many truthful, genuine commendations as possible. In a qualitative research study exploring the practice of commendations, family members shared their belief that commendations were part of the "special, meaningful, and caring relationships that they developed with the therapists [nurses]. Commendations were not techniques . . . but a way of being with people in the world" (Houger Limacher, 2008, p. 99).

Family strengths include clear communication, adaptability, healthy boundaries, support and nurturing among family members, and the use of crisis for growth. You can help the family focus on these strengths rather than on weaknesses.

Providing Information

Families need information from health care providers about developmental issues, health promotion, and illness management, especially if the illness is complex (Hartrick Doane & Varcoe, 2005; Levac et al., 2002). Accurate, timely information is essential for the family to make decisions and cope with difficult situations. Health education is a process by which information is exchanged between nurse and patient/family. Family and patient needs for information may be elicited through direct questioning but are often far more subtle. In this role of educator, you may recognize, for example, that a new father is fearful of cleaning his newborn's umbilical cord stump or that an older woman is not using her cane safely. Respectful communication is required. Nurses often share information subtly: "I notice you are trying to not touch the umbilical cord stump; I see that a lot with other new parents" or "You use the cane the way I did before I was shown a way to keep from falling or tripping over it; do you mind if I show you?" When you assume a humble, caring position instead of coming across as an authority on the subject, this attitude often decreases the patient's defences and invites the family to listen without feeling embarrassed.

Validating or Normalizing Emotional Responses

Validating intense emotions can alleviate a family's feelings of isolation and loneliness and help family members make the connection between a family member's illness and their own emotional response. For example, after a diagnosis of a life-shortening illness, families frequently feel powerless or frightened. It is important to validate these strong emotions as normal and reassure families that they will adjust and learn new ways to cope. You may do this by sharing experiences you have had with other families who faced a similar situation.

Encouraging Illness Narratives

Too often, patients and family members are encouraged to talk only about the medical aspects of their illness rather than the emotional aspects. An **illness narrative** is the person's story of how the illness affects his or her whole being, including emotional, intellectual, social, and spiritual dimensions (Kleinman, 1988; Wright & Bell, 2009). Hearing the person's illness narrative will help you understand the person's/family's strengths and challenges, and the beliefs they hold about their illness experience. This information enables you to offer commendations to the family. Many people also find that telling their story helps them better understand themselves, their experience, and their family's experience. Families also benefit from listening to one another's illness narratives. Prior to meeting with their nurse, families may not have had the opportunity to hear and understand how other family members have suffered in living with illness (Boxes 19-7 and 19-8).

Communicating what it is like to live with individual, separate experiences, particularly the experience of illness, is a powerful human need (Nichols, 1995; Wright, 2005). Frequently, nurses believe that listening entails an obligation to "fix" whatever concerns or problems are raised. However, showing compassion through deep listening and offering commendations are usually more therapeutic or helpful than is offering solutions to problems (Bohn et al., 2003; Houger Limacher, 2003, 2008; Houger Limacher & Wright, 2003; Moules, 2002; Tapp, 2001; Wright & Bell, 2009).

Encouraging Family Support

Family functioning is enhanced by encouraging and assisting family members to listen to each other's concerns and feelings.

* BOX 19-8

EVIDENCE-INFORMED PRACTICE GUIDELINE

Lessons Learned From the Study of Therapeutic Conversations Between Nurses and Family Members Living with Childhood Cancer

- Nurses should offer families the opportunity to gather together in order to speak about the suffering they experience living with illness. Family members may be unable to speak directly with one another about intense emotions and illness suffering.
- The nurse's presence with family members for the purpose of a therapeutic conversation can facilitate a sharing and lessening of suffering. The nurse's ability to create a safe relational space where suffering is explored and contained or held by the nurse is particularly important.
- Careful relational engagement, eliciting the illness narrative, asking circular questions, offering commendations, as well as externalizing inner dialogue are particularly helpful interventions that may help to lessen suffering. The exploration of alternative illness beliefs within the therapeutic conversation opens possibilities for family healing and new ways of living with illness.
- When a family member shares their illness narrative with a nurse, other family members are able to adopt a listening, reflective stance allowing the family to listen and understand each other's experiences differently.

Reference: West, C. H. (2011). Addressing illness suffering in childhood cancer: Exploring the beliefs of family members in therapeutic nursing conversations (unpublished doctoral dissertation). University of Calgary, Calgary.

This assistance can be particularly useful if a family member is embracing some constraining beliefs when a loved one is dying or has died (RNAO, 2006; Wright & Nagy, 1993). For example, a family may believe that talking with the ill person about death and dying would hasten the person's death.

Supporting Family Caregivers

Family members are often afraid of becoming involved in the care of an ill member without a nurse's support. One way you can best provide care is through supporting family caregivers. Without preparation and support, caregiving can be stressful, causing a decline in the health of the caregiver and care receiver or the development of abusive relationships.

Despite its demands, caregiving, whether one spouse caring for the other or a child caring for a parent, can be a positive and rewarding experience (Duxbury et al., 2009). The interpersonal dynamics between family members influence the ultimate quality of caregiving. Nurses can play a key role in helping family members develop better communication and problem-solving skills needed for caregiving.

Researchers have identified variables, such as caregiver and care recipient expectations, that influence caregiving quality. Carruth (1996) studied the concept of **reciprocity**, in which care recipients acknowledged the importance of the caregiver's help, and contributions to a caregiver self-worth. When the caregiver knows that the care recipient appreciates his or her efforts and values the assistance provided, the caregiving relationship is healthier and more satisfying.

Encouraging Respite

Nurses should encourage respite for caregivers, who may feel guilty about or not even recognize their need to withdraw, even temporarily, from caregiving tasks. Sometimes an ill person may be encouraged to accept another person's temporary assistance so that family members can take a break. Whatever the situation, you should remember that each family's need for respite varies.

Providing care and support for family caregivers often involves using available family and community resources for respite. A caregiving schedule is useful when all family members participate, when extended family members share any financial burdens posed by caregiving, and when distant relatives send cards and letters communicating their support. However, it is important to understand the relationship between potential caregivers and care recipients. If the relationship is not a supportive one, community services may be a resource for both the patient and family.

Services that may be beneficial to families include caregiver respite, caregiver support groups, housing and transportation services, food and nutrition services, housecleaning, legal and financial services, home care, hospice, and mental health resources. Before referring a family to a community resource, it is crucial that you are aware of the community services themselves, understand the family's dynamics, and know whether such support is desired or welcomed. A family caregiver may resist help, feeling obligated to be the sole source of support to the care recipient. You must be sensitive to family relationships and help normalize the demands of caregiving and the need for respite.

Interviewing the Family

With a clear conceptual framework for assessment and intervention, you can begin to learn the competencies and skills

needed to conduct family interviews. Family interviews follow the same basic principles as any patient interview (see Chapter 12). However, family interviews have the complexity of more people and multiple relationships. You must develop keen perceptual, conceptual, and executive skills. *Perceptual skills* refer to the ability to make relevant observations. In family interviewing, the nurse must observe multiple interactions and relationships simultaneously. *Conceptual skills* constitute the ability to formulate observations of the entire family and give meaning to those observations. Remember that observations and subsequent judgements are subjective and not conclusive. Executive skills are the actual therapeutic interventions you offer in the context of a family interview. These therapeutic interventions elicit responses from family members and are the basis for further observations and conceptualizations. During an interview, observe and listen for responses from a patient and family to formulate further therapeutic interventions. The type of intervention that you offer depends on your clinical expertise and experience in working with families, as well as the unique challenges and strengths of the family members you are working with. The four stages of a family interview are engagement, assessment, intervention, and termination. Each of these stages will include specific perceptual and executive skills. For more information on the skills and stages of conducting a family interview, see *Nurses and Families: A Guide to Family Assessment and Intervention* (2009), written by Dr. Lorraine Wright and Dr. Maureen Leahey. With these skills, you can assess, explore, and identify strengths and problems in the familiar process of engagement, assessment, intervention, and termination (see Chapter 17). You can also decide to intervene or refer the family to another health provider. These skills should not necessarily be applied to all families. You should tailor the interview to each family's individual context.

It is important to realize that not all family interviews are formal, lengthy processes. Even if you do not have the time for a formal family interview, you can still engage the family in productive, therapeutic conversations. Every conversation between you and the patient or family members improves communication and understanding. Therapeutic conversations can be as short as one sentence or as long as time allows. All therapeutic conversations, regardless of time, have the potential to unite the family (Hougher Limacher & Wright, 2003; McLeod, 2003; West, 2011). Even brief interviews or conversations have tremendous healing potential because they offer families the opportunity to acknowledge and affirm their problems and seek solutions (Hougher Limacher, 2003; Moules, 2002; Tapp, 2001; Wright & Bell, 2009; Wright & Leahey, 2009).

The integration of task-oriented patient care with interactive, purposeful conversation distinguishes a time-effective interview (taking less than 15 minutes). Providing information and involving the family in decision making are integral parts of the therapeutic process. You should search for opportunities to engage in purposeful conversations with families, which may include the following:

- Routinely inviting families to accompany the patient to the unit, clinic, or hospital
- Routinely including families' participation in the admission procedure
- Routinely inviting families to ask questions
- Acknowledging the patient and family's expertise in managing the health problem at home
- Routinely consulting patients and families about their ideas regarding treatment and discharge

✦ KEY CONCEPTS

- Family members influence one another's health beliefs, practices, and status.
- The concept of family is highly individual; thus, you should base care on the patient's definition of family rather than on an inflexible definition of family.
- Family nursing care requires that nurses continually examine the current trends in the Canadian family and its health care implications.
- A healthy, resilient family is able to integrate the need for stability with the need for growth and change. The family can be viewed as context, in which you focus either on the individual patient within the context of his or her family or on the family with the individual as context, or the family can be viewed as patient (family systems nursing), in which you focus on family interactions.
- The CFAM is a conceptual framework that guides you in assessing the structural, developmental, and functional aspects of the family.
- Genograms and ecomaps are structural assessment tools that provide a pictorial image of the family's structure and relation to outside influences.
- Family members as caregivers are often spouses who may be either older adults themselves or adult children trying to work full-time, care for aging parents, and enable children to move out of the home (launch children) successfully.
- Illness and disability often alter expressive functioning and communication within the family.
- Family nursing as relational inquiry is concerned with understanding the family in context (interpersonal, social, geopolitical, historical, environmental context).
- A number of relational capacities that support being in relation with families in a mode of inquiry that balances letting be and emancipator action are key components to family nursing as relational inquiry.
- The CFIM is a companion to the CFAM that guides you in implementing family interventions; it is focused on improving family functioning in three domains: cognitive (thinking), affective (feeling), and behavioural (doing).
- One of the simplest and most effective ways that you can help families is by asking them interventive questions.
- Offering commendations is important because they encourage the family to recognize their strengths and competencies.
- Other nursing interventions to help the family include providing information, validating emotional responses, encouraging patients to provide illness narratives, supporting family caregivers, and encouraging respite for family caregivers.
- Family caregiving is an interactional process that occurs within the context of the relationships among its members.
- Family interviews require you to have perceptual, conceptual, and executive skills; interviews may be formal and lengthy or casual and brief.

✦ CRITICAL THINKING EXERCISES

1. Kathy is a palliative care nurse working with a family of four: Wai-Ling, a 45-year-old single mother; her adolescent sons, Chun and Wang; and Heng, her 76-year-old mother, who is in the last stages of terminal breast cancer. The family has lived together for ten years, ever since they immigrated to Canada from Hong Kong. Heng helped Wai-Ling parent Chun and Wang and supported Wai-Ling when her husband died five

years ago. Wai-Ling has decided to care for her mother in the family's home until Heng dies. Kathy will assist this family in achieving their goal. Kathy has just had in-service training in using CFAM.

- a. What parts of the CFAM should Kathy use when assessing the family's needs?
 - b. How can Kathy help the family achieve their goal of caring for their aging family member at home?
 - c. How can Kathy determine this family's strengths, suffering, and resources?
 - d. What cultural aspects are important to consider for a family who has immigrated to Canada and is now facing the death of a loved one?
 - e. What self-awareness and reflection will support a relational inquiry approach to the assessment and interventions?
2. Dan and Kim divorced seven years ago, and neither has remarried. They have three daughters, aged 10, 12, and 14. At the time of the divorce, Dan was HIV-positive, and has remained so for five years. Kim has had repeated tests and remains HIV-negative. Dan is responding to therapy slowly. Kim and Dan share parenting responsibilities and have a friendly relationship. They have decided it would be easier for the family to live together again so that Dan can actively participate in his children's lives without placing caregiver demands on Kim when the extended family visits overnight. Kim also wants to care for her former husband.
 - a. What family development tasks are important to assess for this family as the members attempt to reunite?
 - b. How should the nurse determine what support services the family needs?
 - c. What assessment questions would be useful to ask in order to assess how the illness is affecting this family? Do family members have any signs of emotional, physical, or spiritual suffering?
 3. Mr. and Mrs. Baillarger, both in their early 50s, are the youngest members of large families. They work full-time and have two teenage children. Both sets of their parents are in their 80s and have chronic health problems. All of their siblings live farther away.
 - a. How can the nurse help Mr. and Mrs. Baillarger access resources to aid in caring for their parents and maintain the responsibilities of their own family unit?
 - b. What developmental tasks does this family have?
 - c. What kinds of questions can you ask to assess the family's emotional and verbal communication (found in CFAM's functional assessment category)?

✦ REVIEW QUESTIONS

1. The nurse must think of family as
 1. Parents and their children
 2. People related by marriage, birth, or adoption
 3. The nuclear family and aunts, uncles, grandparents, and cousins
 4. A set of relationships that the patient identifies as family
2. The patient is remarried, and her two children from a previous marriage live in the same household. Her husband's children visit on the weekend. This is an example of
 1. A nuclear family
 2. A blended family
 3. An extended family
 4. An alternative family

3. Which of the following is *not* a current trend?
 1. The proportion of couples without children at home is increasing.
 2. The proportion of "traditional" families is declining.
 3. The proportions of common-law and lone-parent families are increasing.
 4. The proportion of teenagers giving birth has increased steadily.
4. The primary social context in which health promotion and disease prevention take place is
 1. At educational institutions
 2. From friends and colleagues
 3. From physicians and nurses
 4. In the family
5. Two factors that contribute to the long-term health of a family are
 1. Structure and function
 2. Caregiving and reciprocity
 3. Hardiness and resiliency
 4. Context and system
6. When nurses view the family as patient, their primary focus is on the
 1. Health and development of an individual member existing within a specific environment
 2. Family process and relationships
 3. Family relational and transactional concepts
 4. Family within a system
7. Asking a patient "Who is in your family?" helps you assess
 1. Internal structure
 2. External structure
 3. Context
 4. Instrumental functioning
8. Approaching family from a relational inquiry perspective has a goal of
 1. Professional collaboration
 2. Systematic problem solving
 3. Inquiry to understand the family in context
 4. Circular questions
9. Two of the components of relational inquiry include
 1. Using both open- and closed-ended questions
 2. Applying both a strict assessment format and corresponding interventions
 3. Incorporating both letting be and emancipatory action
 4. Assessing the presenting problem and history of the presenting problem
10. According to the CFAM, emotional communication is a sub-category of
 1. Instrumental functioning
 2. Development
 3. Internal structure
 4. Expressive functioning

11. "What do you think when your husband won't visit your son in the hospital?" is an example of a circular question. Asking the family circular questions is an effective way to
 1. Facilitate change by inviting the family to discover their own answers
 2. Encourage family members to be caregivers
 3. Validate their emotional responses
 4. Target specific yes or no answers
12. During a family interview, the nurse can
 1. Educate the family
 2. Enforce change
 3. Engage a family to assess, explore, and identify strengths and problems
 4. Establish roles

Patient Education

Original chapter by Amy M. Hall, RN, BSN, MS, PhD, CNE

Canadian content written by Nancy A. Edgecombe, RN-NP, BN, MN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Identify appropriate topics for a patient's health education.
- Identify the role of the nurse in patient education.
- Identify the purposes of patient education.
- Use communication principles when providing patient education.
- Describe the domains of learning.
- Identify basic learning needs.
- Identify factors that influence the learning experience.
- Differentiate factors that determine readiness to learn from those that determine the ability to learn.
- Compare and contrast the nursing and teaching processes.
- Write learning objectives for a teaching plan.
- Establish an environment that promotes learning.
- Include patient teaching while performing routine nursing care.
- Use appropriate methods to evaluate learning.

Patient education is one of the most important roles for nurses in any health care setting. Patients and family members have the right to health education so that they can make informed decisions about their health care and lifestyle. Shorter hospital stays, increased demands on nurses' time, increase in numbers of patients with acute conditions, the severity of these acute conditions, and the increase in numbers of chronically ill patients emphasize the importance of high-quality patient education. Initial patient education often takes place in the hospital while patients are in the highly stressful acute stage of their illness and may not be completed at the time of discharge. Hospitals need to have clear guidelines to provide for follow-up. Patient education helps ensure continuity of care as patients move from one health care setting to another. Nurses often clarify information provided by physicians and other health care providers and may become the primary source of information for people adjusting to health problems (Kiger, 2004). In primary health care settings, nurses are often the main source of information about health promotion and illness prevention (Box 20-1).

► BOX 20-1

Supporting Patients With Chronic Disease Through Education

The incidence of chronic disease is increasing with the growing older adult population. Management of chronic illness, such as chronic obstructive pulmonary disease (COPD), includes a significant primary health component, focusing on the promotion of optimal health. Patient education can positively influence health behaviour, minimize symptoms, and assist patients to maintain optimal health.

Nurse-led clinics can educate patients about their disease, its consequences, and its management. The goal of patient education is to support patients in lifestyle changes and is aimed at maintaining and where possible improving their health. It is a tool necessary for effective patient self-care. Education in primary health care is not limited to providing facts and information. It also addresses the emotional component of chronic illness and acknowledges feeling and affective reactions to being chronically ill. Taking a patient-centred care approach, the patient is a partner in the education process. This requires developing a professional therapeutic relationship to enable the patient to improve his or her knowledge, acquire skills, and adapt behaviours as a means to “restore, maintain and improve their health” (Zakrisson & Hägglund, 2010, p. 148).

By using a motivational model such as the Transtheoretical Model (TMM), the nurse can engage the patient through an individual process of lifestyle change. The nurse acknowledges that patients may not be ready to change some aspects of their lives, despite health risks. Activities focus on motivating and enabling the patient through the stages of change and providing stage-appropriate educational material. This respects the patient's autonomy and focuses efforts to where they are most likely to be successful. Acknowledging the patients' ownership of their behaviour and taking a motivational approach to behaviour change promotes the patients' self-efficacy, and as a result success is more likely. Success with lifestyle change in one area may increase readiness in other areas.

From Zakrisson, A., & Hägglund, D. (2010). The asthma/COPD nurses' experience of educating patients with chronic obstructive pulmonary disease in primary health care. *Scandinavian Journal of Caring Sciences*, 24(1), 147–155. doi:10.1111/j.1471-6712.2009.00698.x.

The general public has become more assertive in seeking knowledge, understanding health, and finding resources available within the health care system. Nurses need to assist patients in navigating the vast amount of information available to them, through all forms of media. The Internet and other forms of technology (telehealth, e-health) provide nurses and patients with vast amounts of information, some reliable and some not. Patients need guidance regarding the selection of current and reliable resources. Nurses must be able to discuss with patients the criteria for evaluating sources for validity and reliability. The teaching material provided by nurses must honour the copyright rules and must reference both written information and illustrations that are used to support patient learning.

You need to be mindful of the increasing emphasis on “scientific” evidence and the diminished focus on other kinds of evidence of the efficacy or effectiveness of therapeutic interventions. You need to have a broad perspective of what constitutes meaningful evidence to support the significance of testimonials, lived experiences, and other ways of knowing. Because critical thinking is essential in nursing care, you need to be mindful that knowledge is limited, beliefs change, and conclusions are temporary. A well-designed, comprehensive

teaching plan that meets a learner's needs can reduce health care costs, improve quality of care, help patients gain optimal wellness, and increase independence (Bastable, 2006).

Goals of Patient Education

The goal of patient education is to assist individuals, families, or communities in achieving optimal health (Edelman & Mandle, 2010). Education is an important component of primary health care; it helps individuals, families, and communities to develop the knowledge, understanding, and skills necessary to maintain and improve their health; reduces hardship; helps contain health care costs; and enables people to take control of their own health (Hogan, 2008; World Health Organization [WHO], 1986). Patient education has three main goals (Box 20-2):

- Maintaining and promoting health and preventing illness
- Restoring health
- Optimizing quality of life with impaired functioning

Maintaining and Promoting Health and Preventing Illness

In the home, clinic, or other community health care setting, you provide information and skills that people need to maintain and improve their health (see Box 20-2). For example, in prenatal classes, nurses teach expectant parents about fetal development and physical and psychological changes during pregnancy. They also teach about the importance of healthy food choices, exercise, and avoiding substances that might harm the fetus. Greater knowledge can result in better health. When patients become more health conscious, they are more likely to seek early diagnosis of health problems (Redman, 2007). The growth and development of the Internet has allowed health information and resources to be accessed directly by patients.

Restoring Health

Many patients seek information and skills that will help them regain or maintain their health (see Box 20-2). However, patients who find it difficult to adapt to illness may be more passive. You will learn to identify barriers to learning, to recognize patients' willingness to learn, and to help motivate interest in learning (Redman, 2007).

The family can be a vital part of a patient's return to health and may need to know as much as the patient. If you exclude the family from a teaching plan, conflicts may arise. For example, if the family does not understand a patient's need to regain independent function, their efforts may encourage dependency and slow recovery. You should assess the patient-family relationship before involving the family in a teaching plan (see Chapter 19).

Coping With Impaired Functioning

Some patients must learn to cope with permanent health alterations. For example, a patient who loses the ability to speak after surgery of the larynx must learn new ways to communicate. A patient with severe heart disease must learn to modify risk factors that might cause further heart damage. After the patient's needs are identified and the family has displayed willingness to help, you teach family members to assist the patient with health care management (e.g., giving medications through gastric tubes and performing passive range-of-motion exercises).

► BOX 20-2 Topics for Health Education**Health Maintenance and Promotion and Illness Prevention****Educate patients about:**

First aid
 Health resources (e.g., Internet)
 Avoidance of risk factors (e.g., smoking, alcoholism, obesity)
 Stress management
 Typical growth and development patterns
 Proper hygiene
 Immunizations (e.g., recommendations, risks and benefits)
 Prenatal care and normal child-bearing
 Nutrition
 Exercise
 Safety (in home and health care setting)
 Screening for common conditions (e.g., blood pressure, poor vision, cholesterol level)
 Behaviour modification to change risky behaviours (e.g., smoking cessation, treatment for substance abuse)

Restoration of Health**Educate patients about:**

Patient's disease or condition
 Anatomy and physiology of body system affected by disease or condition
 Cause of disease
 Origin of symptoms
 Expected effects on other body systems
 Prognosis
 Limitations on function
 Rationale for treatment
 Medications
 Alternative therapies (evidence regarding risks and benefits)
 Tests and therapies
 Nursing measures
 Surgical intervention
 Expected duration of care
 Hospital or clinic environment
 Hospital or clinic staff
 Long-term care implications
 Methods for patient's participation in care
 Limitations imposed by disease or surgery

Optimizing Quality of Life When Functions Are Impaired**Educate patients about:**

Home care
 Medications
 Intravenous therapy
 Diet
 Activity
 Self-help devices
 Rehabilitation of remaining function
 Allied health services (e.g., physiotherapy, occupational therapy, speech therapy)
 Prevention of complications
 Knowledge of risk factors
 Implications of noncompliance with therapy
 Environmental alterations
 Self-help and support groups

*** BOX 20-3 RESEARCH HIGHLIGHT****The Effectiveness of Nurse-Directed Patient Education****Research Focus**

Patients living with venous leg ulcers need education about their diagnosis and related care to prevent multiple hospitalizations and promote optimal functioning.

Research Abstract

Kapp and colleagues (2010) wanted to know if a Leg Ulcer Prevention Program (LUPP), a multidisciplinary approach to patient education about the prevention and management of venous leg ulcers, was effective. LUPP provided an innovative approach to educating patients about venous leg ulcers and ulcer prevention and treatment. The program consisted of six weekly sessions in the patient's home by a visiting nurse. Each session consisted of a short computerized multimedia presentation, a written version of the presentation, and a summary sheet of the main message and activities relevant to the session content. Following completion of the six sessions, patients were found to be more knowledgeable about the cause of venous ulcers and how to prevent and treat leg ulcers. Health behaviours that were improved following the sessions included increase in walking and recommended exercises, elevation of legs when sitting, and improved skin care. Nutrition considerations such as diet and fluids intake were not influenced by the sessions. The proper use of compression therapy was also improved following the program. Patients indicated they found the sessions informative and valuable and appreciated the multiple methods of information delivery with support from the nurse.

Research Highlights

- A multimethod approach enhanced patients' understanding and health behaviours relating to the prevention and management of venous leg ulcers.
- Use of compression therapy improved following education sessions.
- The use of multiple methods of information delivery was effective with onsite nurse support.

**Teaching and Learning**

Teaching is an interactive process that promotes learning. Teaching and learning generally begin when a person identifies a need for knowing or acquiring an ability to do something. A nurse-teacher provides information that prompts the patient to engage in activities that lead to a desired change (Box 20-3). Teaching is most effective when it addresses the learner's needs, learning style, and capacity. The teacher assesses these needs by asking questions, observing the patient, and determining the patient's interests. With successful teaching, patients can learn new skills or change existing attitudes (Redman, 2007).

Role of the Nurse in Teaching and Learning

Nurses have an ethical responsibility to teach their patients about health enhancement (Redman, 2005, 2007). The

Canadian Nurses Association's (2008) *Code of Ethics* indicates that patients have the right to make informed decisions about their care. The information that patients need to make such decisions must be accurate, complete, and relevant to their needs. You should anticipate patients' needs for information on the basis of their overall condition (physical, mental, emotional, spiritual), identified risks, and interdisciplinary treatment plans. Nurses often clarify information provided by physicians and other health care providers and may become the primary source of information for adjusting to health problems (Bastable, 2006).

Patients and their families often ask nurses for health information. It is easy to identify the need for teaching when patients request information. However, in some cases, the need for information may be less apparent. You must observe and listen carefully to determine patients' needs for information and learning. When you value education and ensure that your patients learn necessary information, patients are better prepared to assume health care responsibilities. To be an effective educator, you must do more than just pass on facts; you must determine what patients need to know, find time when they are ready to learn, and evaluate the impact of patient education on patient outcomes (Bastable, 2006, 2008; Redman, 2007).

Teaching as Communication

Effective teaching depends on effective communication (see Chapter 17). To be a good teacher, you must listen empathetically, observe astutely, and speak clearly. Many intrapersonal variables—including attitudes, values, culture, emotions, and knowledge—influence both the nurse's and patient's styles and approaches. Both you and the patient are also affected by the patient's motivation and ability to learn, which depend on physical and psychological health, education, developmental stage, and previous knowledge.

Domains of Learning

Learning occurs in three domains: cognitive (understanding), affective (attitudes), and psychomotor (motor skills); (Anderson & Krathwohl, 2001; Bloom, 1956). Any topic to be learned may involve one domain, all domains, or any combination of the three. For example, patients with diabetes must learn how diabetes affects the body and how to control blood glucose levels for better health (cognitive domain). They must also learn to accept the chronic nature of diabetes by learning positive coping mechanisms (affective domain). Finally, many patients with diabetes must learn to test their blood glucose levels at home. This requires learning how to use a glucose meter (psychomotor domain). By understanding each learning domain, you can select appropriate teaching methods (Box 20-4).

Cognitive Learning

Cognitive learning includes all intellectual behaviours and requires thinking (Anderson & Krathwohl, 2001). In the hierarchy of cognitive behaviours, the simplest behaviour is remembering, whereas the most complex is creating. Cognitive learning includes the following:

- Remembering: the ability to retrieve knowledge from long-term memory
- Understanding: the ability to construct the meaning of learned material

► BOX 20-4

Appropriate Teaching Methods Based on Domains of Learning

Cognitive

Discussion (One-on-One or Group)

May involve nurse and one patient or nurse with several patients
Promotes active participation and focuses on topics of interest to patient

Facilitates peer support

Enhances application and analysis of new information

Storytelling

Can involve individual or group

Facilitates cultural relevance and safety

Enhances application of new information to a familiar context

Lecture

Is more formal method of instruction because it is teacher controlled

Helps learner acquire new knowledge and gain comprehension

Question-and-Answer Session

Is designed specifically to address patient's concerns

Assists patient in applying knowledge

Role Play and Discovery

Encourages patient to actively apply knowledge in controlled situation

Promotes synthesis of information and problem solving

Independent Projects (e.g., Computer-Assisted Instruction) and Field Experience

Assists patient to assume responsibility for learning at own pace

Promotes analysis, synthesis, and evaluation of new information and skills

Affective

Role Play

Encourages expression of values, feelings, and attitudes

Discussion (Group)

Enables patient to acquire support from other people in group

Encourages patient to learn from other people's experiences

Promotes responding, valuing, and organizing

Discussion (One-on-One)

Facilitates discussion of personal, sensitive topics of interest or concern

Psychomotor

Demonstration

Provides presentation of procedures or skills by nurse

Encourages patient to model nurse's behaviour

Allows nurse to control questioning during demonstration

Practice

Enables patient to perform skills by using equipment in a controlled setting

Allows repetition

Return Demonstrations

Enables patient to perform skill as nurse observes

Provides excellent source of feedback and reinforcement

Independent Projects and Games

Require teaching method that promotes adaptation and initiation of psychomotor learning

Enable learner to use new skills

- Applying: the use of abstract, newly learned ideas in a practical situation
- Analyzing: the breaking down of information into organized parts and determining how the parts relate to one and other
- Evaluating: making judgements based on criteria and standards
- Creating: combining elements to form a coherent and functional whole

Affective Learning

Affective learning concerns expressions of feelings and acceptance of attitudes, opinions, or values. Values clarification (see Chapter 7) is an example of affective learning. The simplest behaviour in the affective learning hierarchy is receiving, and the most complex is characterizing (Krathwohl et al., 1964).

- Receiving: the willingness to attend to another person's words
- Responding: active participation through listening and reacting verbally and nonverbally
- Valuing: attachment of worth to an object, concept, or behaviour, demonstrated by the learner's actions
- Organizing: development of a value system by identifying and organizing values and resolving conflicts
- Characterizing: action and response with a consistent value system

Psychomotor Learning

Psychomotor learning involves acquiring skills that require the integration of mental and muscular activity, such as the ability to walk or to use an eating utensil. The simplest behaviour in the hierarchy is perception and the most complex is origination (Rankin & Stallings, 2005; Redman, 2007).

- Perception: awareness of objects or qualities through the use of sense organs
- Set: a readiness (mental, physical, or emotional) to take a particular action
- Guided response: the performance of an act under the guidance of an instructor, involving imitation of a demonstrated act
- Mechanism: a higher level of behaviour by which a person gains confidence and skill in performing a behaviour that is more complex or involves several more steps than does a guided response
- Complex overt response: the smooth and accurate performance of a motor skill that requires a complex movement pattern
- Adaptation: the ability to change motor response when unexpected problems occur
- Origination: use of existing psychomotor skills and abilities to perform a highly complex motor act that involves creating new movement patterns

Basic Learning Principles

Before nurses can teach, they must understand how people learn. Learning depends on the learning environment and on the individual's ability to learn, learning style, and motivation to learn. Learning takes place both in formal learning sessions, which involve planned learning activities, and in teachable moments, which allow you to spontaneously take advantage of teaching opportunities as they occur in the day-to-day contact with the patient.

Learning Environment

Patient education takes place in a variety of settings: the patient's home, community centres, classrooms, and hospital rooms. The ideal environment for learning is a well-lit, well-ventilated room with appropriate furniture and a comfortable temperature. A quiet setting with few distractions and interruptions helps concentration. You can provide privacy even in a busy hospital by closing cubicle curtains or taking the patient to a quiet spot. In the home, a bedroom might separate the patient from household activities. If the patient desires, family members or significant others may share in discussions. However, some patients may be reluctant to discuss their illness when other people, even close family members, are in the room. An ideal environment is not always achievable, however, and rather than miss a teachable moment, you can adapt the environment as much as possible to provide privacy and minimize distractions.

Ability to Learn

The ability to learn depends on emotional, intellectual, and physical capabilities and on developmental stage. If a patient's learning ability is impaired, you should modify or postpone teaching activities.

Emotional Capability. Emotions can aid or prevent learning. Mild anxiety may help a person focus. However, stronger levels of anxiety can be incapacitating, creating an inability to attend to anything other than to relieve the anxiety. The prospect of change makes many people anxious. Seriously ill people, who are faced with multiple losses, may be extremely anxious and distressed. Nurses must be sensitive to a patient's level of anxiety. If a person is incapacitated by anxiety, you need to find a way to alleviate the anxiety. This may mean teaching relaxation techniques before attempting to teach a task or a procedure.

Intellectual Capability. Patients have different levels of intellectual ability. You must assess the patient's knowledge and intellectual level before beginning a teaching plan. For example, measuring liquid or solid food portions requires the ability to perform mathematical calculations. Reading a medication label or discharge instructions requires reading and comprehension skills. Following directions when performing self-care in accordance with limitations requires comprehension and application skills.

Physical Capability. The ability to learn often depends on physical health. To learn psychomotor skills, a patient must possess the necessary strength, coordination, and sensory acuity. You should not overestimate the patient's physical ability. The following physical attributes are necessary for learning psychomotor skills:

- Size (height and weight adequate for performing the task or using the equipment, such as crutch walking)
- Strength (ability of the patient to follow a strenuous exercise program)
- Coordination (dexterity needed for complicated motor skills, such as using utensils, changing a bandage, or opening a medication container)
- Sensory acuity (visual, auditory, tactile, gustatory, and olfactory resources needed to receive and respond to messages taught)

Any physical condition (e.g., pain, fatigue, hunger) that depletes energy also impairs the ability to learn. For example, a patient in a weakened state who has just spent hours undergoing diagnostic tests is likely to be too fatigued to learn.

► BOX 20-5

Teaching Methods Based on Patient's Developmental Capacity

Infant

Maintain consistent routines (e.g., feeding, bathing).
Hold infant firmly while smiling and speaking softly, to convey sense of trust.
Have infant touch different textures (e.g., soft fabric, hard plastic).

Toddler

Use play to teach procedure or activity (e.g., handling examination equipment, applying bandage to doll).
Offer picture books that describe a story of children in a hospital or clinic.
Use simple words such as "cut" instead of "laceration," to promote understanding.

Preschooler

Use role playing, imitation, and play to make learning fun.
Encourage questions and offer explanations; use simple explanations and demonstrations.
Encourage several children to learn together through pictures and short stories about how to perform hygiene.

School-Age Child

Teach necessary psychomotor skills. (Complicated skills, such as learning to use a syringe, may take considerable practice.)
Offer opportunities to discuss health problems and answer questions.

Adolescent

Help adolescent learn about feelings and need for self-expression.
Collaborate with adolescent on teaching activities.
Let adolescent make decisions about health and health promotion (safety, sex education, substance abuse).
Use problem solving to help adolescent make choices.

Young or Middle-Age Adult

Encourage participation in teaching plan by setting mutual goals.
Encourage independent learning.
Offer information so that adult can understand effects of health problem.

Older Adult

Teach when patient is alert and rested.
Involve adult in discussion or activity.
Focus on wellness and the person's strength.
Use approaches that enhance sensorially impaired patient's reception of stimuli (see Chapter 47).
Keep teaching sessions short.

Nurses must assess the patient's energy level by noting the patient's willingness to communicate, the degree of activity initiated, and the patient's responsiveness to questions. You may halt teaching if the patient needs rest.

Developmental Stage. Age and stage of development affect the ability to learn (Box 20-5). Without proper biological, motor, language, and personal-social development, many types of learning cannot take place.

Learning in Children. As a child matures, intellectual growth progresses from concrete to abstract. Therefore, information should be understandable, and the expected outcomes should be realistic and based on the child's developmental

Figure 20-1 The nurse uses a developmentally appropriate toy syringe to teach about immunization to the school-aged children.

stage. Developmentally appropriate teaching aids should also be used (Figure 20-1).

Adult Learning. Many adults are independent, self-directed learners. However, they may become dependent in new learning situations. Adults typically learn more successfully when they are encouraged to use past experiences to solve problems. Adult patients and nurses should collaborate on educational topics and goals. Needs or issues that are important to the adult should be addressed early in the teaching-learning process. Ultimately, adults must accept responsibility for changing their own behaviours. Assessing what the adult patient currently knows, teaching what the patient wants to know, and setting mutual goals will improve the outcomes of care and education (Bastable, 2008).

Learning Style and Preference

People have different learning styles. Everyone processes information differently by seeing and hearing, reflecting and acting, reasoning logically and intuitively, and analyzing and visualizing. Some people are visual learners; they learn best by watching. Audiovisual presentations and visual demonstrations often work best for this type of learner. Other people are kinesthetic learners; they learn best when they are able to manipulate tools and find out how they work. Some people learn by taking detailed notes; others prefer to only listen. Some people need to be engaged in activities and discussion in order to learn effectively. Others may be too shy to enjoy this type of learning and prefer to learn from an orderly, structured presentation.

Environmental, social, emotional, psychological, and physical stimuli affect people differently. Some people prefer complete silence in the learning environment, whereas others prefer background sounds. Some prefer to learn in a group; others, on their own. Different people prefer different times of the day for learning experiences.

When developing teaching plans, you should assess the favoured learning style and preferences of the patient. With groups, it may not be possible to address every patient's preferences. However, including a combination of approaches to meet multiple learning styles can ensure that most people's learning preferences are met (Bastable, 2006). When the patient

is having difficulty with learning, you should consider a change to accommodate a different learning style.

Motivation to Learn

Motivation is a person's desire or willingness to learn, and it influences a person's behaviour (Redman, 2007; Box 20-6). If a person is not ready or does not want to learn, learning is unlikely to occur. The stimuli for motivation vary between

individuals and may be social, task mastery, or physical in nature. *Social motives* reflect a need for connection, social approval, or self-esteem. For example, the motivation to exercise may be linked to the social aspects of the exercise activities (Heading, 2008). *Task mastery motives* are driven by desire for achievement. For example, a high school student with diabetes begins to test blood glucose levels and determine insulin dosages before leaving home and establishing independence. The desire to live independently and manage the disease provides the motivation to master the task or skill. After succeeding at a task, a person is usually motivated to achieve more. *Physical motives* come from a desire to maintain and improve health. Patients motivated by the need to survive or overcome hardship are often more motivated than those who wish merely to improve their health (Rankin & Stallings, 2005). For example, a patient who has undergone a leg amputation may be extremely motivated to learn to use assistive devices, whereas a patient who is overweight but otherwise healthy may not be motivated to exercise.

Many people do not adopt new health behaviours or change unhealthy behaviours unless they perceive a disease as a threat, overcome barriers to changing health practices, and see the benefits of such changes (Pender et al., 2011). Thus, a patient with lung disease may continue to smoke. An obese patient may worsen a heart condition by refusing to follow a low-fat diet.

Motivation and Social Learning Theory. Health education often involves changing people's attitudes and values. Change can occur only when education plans and interventions are based on sound learning theories. A number of theories address the complex patient education process (Bastable, 2008; Redman, 2007). One of these is **social learning theory**, which helps educators understand learners and develop interventions that enhance motivation and learning (Bandura, 2001; Bastable, 2008; Wood, 2008).

When people believe that they can execute a particular behaviour, they are more likely to perform the behaviour consistently and correctly (Bandura, 1997). *Self-efficacy*, a social learning theory concept, is a person's perceived ability to successfully complete a task. Beliefs about self-efficacy arise from four sources: verbal persuasion, vicarious experiences, enactive mastery experiences, and physiological and affective states (Bandura, 1997). Understanding these sources lets nurses develop appropriate interventions. For example, a nurse teaching a boy with asthma to use an inhaler expresses positive reinforcement (verbal persuasion), by encouraging him to use the inhaler himself. The nurse then demonstrates to the boy how to use the inhaler (vicarious experience). The boy successfully uses the inhaler by himself (enactive mastery experience). As the boy is able to control his asthma by using the inhaler, the nurse gives him positive feedback, which further enhances his confidence to use the inhaler (physiological and affective states). Interventions such as these enhance perceived self-efficacy, which in turn improves the achievement of desired outcomes.

Motivation and Transtheoretical Model of Change.

Health education may involve changes in behaviour. Behavioural change is often challenging and difficult. It involves a process that occurs over time through a series of stages. By identifying the patient's stage of change and focusing learning activities to match the patient's stage, you facilitate the learner's motivation to change and his or her transition from one stage to the next. Five stages have been identified and used in

BOX 20-6 NURSING STORY

"To Take or Not to Take"

In preparation for a trip to Vietnam and Cambodia, Mr. and Mrs. Bennet visited a travel clinic, which recommended that they update their immunization (diphtheria-pertussis-tetanus, hepatitis A, typhoid) and take antimalarial drugs for the Cambodia portion of the trip (atovaquone/proguanil [Malarone], one pill daily starting one day before stay and continuing during stay and one week after). When they came in for their immunizations, they expressed some concerns about taking the antimalarial drugs. They had been talking to friends who told them these antimalarial drugs had severe side effects and caused hallucinations. They had investigated several Internet sites that their friends had recommended; these sites indicated that antimalarial drugs were not required for where they were going. Mrs. Bennet e-mailed the Cambodian Consulate in Canada and was told that malaria was not a concern where they were going.

Assessment

- Concerned about health but received mixed messages about the need for antimalarial drugs
- Concerned about serious side effects of drugs
- Motivated to learn

Plan

- Discussed with Mr. and Mrs. Bennet criteria evaluating Web sites for health information (author, age, conflict of interest, whether evidence informed rather than opinion based)
- Provided list of reliable travel health sites (Health Canada, World Health Organization, US Centers for Disease Control and Prevention)
- Identified other measures to reduce risk of contracting malaria (using mosquito repellent, limiting time outside at night, staying in air-conditioned rooms or mosquito nets, wearing protective clothing)
- Discussed various drugs used for malaria and the incidence and type of side effects
- Explored the risk of not taking medication and implications of contracting malaria
- Identified other resources of information (travel agents, pharmacists)

Outcome

Mr. and Mrs. Bennet visited several reliable sources on the Internet and talked to their pharmacist. They identified several strategies to minimize exposure to mosquitoes on their travels. Mr. Bennet learned that the risk of side effects from the Malarone was minimal and decided to take the drug. Mrs. Bennet also recognized that the risk for side effects was minimal; however, because of her concern about those side effects, she decided not to take the Malarone. She was more comfortable taking the risk because she understood that if she developed a high fever and flu-like illness at any time up to a year after the trip, she had to seek immediate medical attention.

smoking cessation activities (Prochaska & DiClemente, 1992; Stephenson & Allen, 2007):

- Precontemplation: is unaware of need for change and has no intention of changing behaviour
- Contemplation: is aware of need for change and intends to change behaviour sometime in the future
- Preparation: alters behaviour in minor ways with the intention to make substantive changes in the immediate future
- Action: modifies behaviour and experiences in order to make sustainable change
- Maintenance: focuses on not reverting to previous behaviour and on solidifying new behaviours

Integrating the Nursing and Teaching Processes

The nursing and teaching processes are related (Redman, 2007) and usually take place concurrently. Like the nursing process, the teaching process requires assessment, nursing diagnosis, planning, implementation, and evaluation. However, the processes are not exactly the same: the nursing process is broader. For example, determining a patient's health needs requires assessing all data sources. The teaching process is focused on data sources that reveal the patient's learning needs, willingness and ability to learn, and available teaching resources. The teaching process is especially useful for teaching large groups, where individual learning needs and styles may vary. Table 20-1 compares the teaching and nursing processes.

The teaching process requires assessment. The patient's ability to learn, motivation, and needs should be assessed and analyzed. A diagnostic statement specifies the information or skills that the patient requires. You set specific **learning objectives** (i.e., what the learner will be able to do after successful instruction) and implement the teaching plan by using teaching and learning principles to ensure that the patient acquires knowledge and skills. Finally, the teaching process requires an evaluation of learning; this evaluation is based on learning objectives.

❖ Assessment

During assessment, you determine the patient's health care needs (see Chapter 12). The patient may reveal a need for health care information, or you may identify a need for education. Learning needs identified by both the patient and the nurse determine the content to be learned. By performing an effective assessment, you can individualize instruction for each patient (Polzein, 2007). Ask specific questions to assess a patient's unique learning needs (Box 20-7).

Learning Needs

Most patients can identify at least some of their own learning needs. Effective questioning and assessment tools help you determine a patient's perceived learning needs. By listening carefully and using open-ended and closed-ended questions (see Chapter 17), nurses can often find out what a patient's needs are. Because a patient's health status is dynamic, assessment is an ongoing activity. Assess the following:

- Information or skills needed by the patient to perform self-care and to understand the implications of a health problem. (Health care team members anticipate learning needs related to specific health problems. For example, you teach an adolescent boy to perform testicular self-examination.)

► TABLE 20-1

Comparison of the Nursing and Teaching Processes

Basic Steps	Nursing Process	Teaching Process
Assessment	Collect data about patient's physical, psychological, social, cultural, developmental, and spiritual needs from patient, family, diagnostic tests, medical record, health history, learning style, and literature.	Gather data about patient's learning needs, motivation, ability to learn, and teaching resources from patient, family, learning environment, medical record, health history, and literature.
Nursing diagnosis	Identify appropriate nursing diagnoses based on assessment findings, including deficits.	Identify patient's learning needs on basis of three domains of learning.
Planning	Develop individualized care plan. Set diagnosis priorities on the basis of patient's immediate needs. Collaborate with patient on care plan.	Establish learning objectives, stated in behavioural terms. Identify priorities regarding learning needs. Collaborate with patient on teaching plan. Identify type of teaching method to use.
Implementation	Perform nursing care therapies. Include patient as active participant in care. Involve family or significant other in care as appropriate.	Implement teaching methods. Actively involve patient in learning activities. Include family or significant other in participation as appropriate.
Evaluation	Identify success in meeting desired outcomes and goals of nursing care. Alter interventions as indicated when goals are not met.	Determine outcomes of teaching-learning process. Measure patient's ability to achieve learning objectives. Reinforce information as needed.

- Patient's experiences that influence the need to learn.
- Information that the family members or significant others require to support the patient's needs. (The amount of information needed depends on the extent of the family's role in helping the patient.)

► BOX 20-7 Nursing Assessment Questions**Ask Patients**

What do you want to know?
 What do you know about your illness and your treatment plan?
 How does (or will) your illness affect your current lifestyle?
 What barriers currently exist that are preventing you from managing your illness the way you would like to manage it?
 What cultural or spiritual beliefs do you have regarding your illness and the prescribed treatment?
 What experiences have you had that are similar to what you are experiencing now?
 Together we can choose the best way for you to learn about your disease. How can I best help you?
 What role do you believe your health care provider should take in helping you manage your illness or maintain health?
 When you learn new information, do you prefer to have the information given to you in pictures or written down in words?
 When you give someone directions to your house, do you tell the person how to get there, write out the instructions, or draw a map?
 How involved do you want your family to be in the management of your illness?

Ask Family Members

When are you available to help, and how do you plan to help your loved one?
 Your spouse needs some help. How do you feel about learning how to assist him [her]?

Ability to Learn

The ability to learn can be impaired by many factors, including body temperature, electrolyte levels, oxygenation status, and blood glucose level. Several factors may influence a patient at one time. You assess the patient's ability to learn by considering the following:

- Physical strength, movement, dexterity, and coordination (you determine the patient's ability to perform skills)
- Sensory deficits that may affect the ability to understand or follow instruction (see Chapter 47)
- Reading level (reading level can be difficult to assess because functional illiteracy is often easy to conceal; one way to assess a patient's reading level and level of understanding is to ask the patient to read instructions from a teaching brochure and then explain its meaning)
- Developmental level (developmental level influences teaching approaches [see Box 20-5])
- Cognitive function (cognitive function includes memory, knowledge, association, and judgement)

Motivation to Learn

You ask questions that identify a patient's motivation level, which help you determine whether the patient is prepared and willing to learn. You assess the patient's motivation by studying the following:

- Behaviour (e.g., attention span, tendency to ask questions, memory, and ability to concentrate during the teaching session)
- Health beliefs and perception of a health problem and the benefits and barriers to treatment (e.g., you ask a patient with coronary artery disease, "Explain how heart disease

will affect you over time. What is the value of eating a low-fat diet?")

- Perceived ability to complete a required healthy behaviour
- Desire to learn
- Attitudes about health care providers (e.g., role of patient and nurse in making decisions, such as your asking, "In what way can I best help you?")
- Knowledge of information to be learned (the patient must play an active role in seeking health-related information)
- Pain, fatigue, anxiety, or other physical symptoms that can interfere with the ability to maintain attention and participate (in acute care settings, a patient's physical condition can easily detract from learning)
- Sociocultural background (a patient's beliefs and values about health and various therapies may be influenced by sociocultural norms or tradition [see Chapter 9]; educational efforts can be especially challenging when patients and educators do not speak the same language)
- Learning style preference (patients who learn better by seeing and hearing may benefit from a video; patients who learn best by reasoning logically and intuitively may learn better if presented with written material that they can analyze and discuss with others)

Teaching Environment

You assess the following factors when choosing a teaching environment:

- Distractions or persistent noise (a quiet area should be set aside for teaching)
- Comfort of the room, including ventilation, temperature, lighting, and furniture
- Room facilities and available equipment

Resources for Learning

Assessment of resources includes a review of available teaching tools. If a patient requires family support, you evaluate the readiness and ability of family and friends to learn to care for the patient, and you review resources in the home. You assess the following:

- Patient's willingness to have family members involved in the teaching plan and care (information about the patient's health care is confidential unless the patient chooses to share it)
- Family members' perceptions and understanding of the patient's illness and its implications (family members and patients' perceptions should match; otherwise, conflicts may arise in the teaching plan)
- Family's willingness and ability to participate in care (family members must be responsible, willing, and able to assist in care activities, such as bathing or administering medications)
- Resources in the home (these resources include health care equipment, access to technology, and a suitable rearrangement of rooms)
- Teaching tools, including brochures, audiovisual materials, or posters. Printed material should present current and easy-to-understand information that matches the patient's reading level.

❖ Nursing Diagnosis

After assessing the patient's ability and need to learn, you interpret data to form an accurate diagnosis. This diagnosis

ensures that teaching will be goal directed and individualized. If a patient has several learning needs, the nursing diagnoses guide priority setting. By classifying diagnoses according to the three learning domains, you can focus on subject matter and teaching methods. Examples of nursing diagnoses that indicate a need for education include the following:

- *Ineffective health maintenance*
- *Health-seeking behaviours*
- *Impaired home maintenance*
- *Deficient knowledge*
- *Ineffective therapeutic regimen management*
- *Ineffective community therapeutic regimen management*
- *Ineffective family therapeutic regimen management*

When health care problems can be managed through education, the diagnostic statement is *deficient knowledge*. For example, an older adult may be unable to manage a medication regimen because of the number of medications that must be taken at different times of the day. Education may improve the patient's ability to schedule and take the medications.

Some nursing diagnoses also indicate that teaching is inappropriate. You may identify conditions that hinder learning (e.g., nursing diagnosis of pain or activity intolerance). In these cases, you should delay teaching until the nursing diagnosis is resolved or the health problem is controlled.

❖ Planning

After identifying a patient's learning needs and making a nursing diagnosis, you develop a teaching plan, set goals and expected outcomes, and work with the patient to select a teaching method (Box 20-8). Expected outcomes or learning objectives determine which teaching strategies and approaches are appropriate. Patient participation is essential.

Developing Learning Objectives

Learning objectives identify the expected outcome of instruction and establish learning priorities. Objectives help you manage time and resources.

Objectives are either for a short term or a long term. Short-term objectives meet the patient's immediate learning needs, such as needing knowledge about an upcoming test. Long-term objectives, which are often broader, help a patient adapt to a long-term challenge. Learning objectives, which will guide the teaching plan, include the same criteria as outcomes in a nursing care plan:

- Singular behaviours
- Observable or measurable content
- Timing or conditions under which the objective is measured
- Goals mutually set by the nurse and patient

Each objective focuses on a single behaviour that will determine the patient's ability to meet health care outcomes. A behavioural objective contains an active verb, describing what the learner will do after the objective is met (e.g., "*will administer an injection*"). Behavioural objectives are measurable and observable and indicate how learning will be evidenced (e.g., "*will perform three-point crutch gait*"). The objective describes precise behaviours and content. Nurses should avoid vague or nonspecific objectives that do not explain what the learner is to do.

An objective is more precise when it describes the conditions or timing under which the behaviour occurs. Conditions

and time frames should be realistic and designed for the learner's needs (e.g., "*will identify the side effects of medication by discharge*"). It also helps to consider conditions under which the patient or family will perform the behaviour (e.g., "*will walk from bedroom to bathroom, using crutches*"). You set criteria for acceptable performance on the basis of the desired level of accuracy, success, or satisfaction. For example, "*a patient undergoing therapy for a fractured leg will walk on crutches to the end of the hall within three days.*" Criteria are more acceptable when the teacher and learner establish them mutually. However, you serve as a resource in setting the minimum criteria for success.

After formulating objectives, you and the patient establish a teaching plan. You integrate basic teaching principles and develop a well-timed, organized teaching plan.

Setting Priorities

The teaching plan is prioritized according to the patient's immediate needs, nursing diagnoses, learning objectives, main concerns, anxiety level, and the time available to teach.

Timing

When is the right time to teach? Before a patient is hospitalized? When a patient enters a clinic or a long-term care facility? At discharge? At home? All of these times are correct because patients continue to have learning needs and opportunities as long as they stay in the health care system. You should plan to teach when a patient is most attentive, receptive, and alert. However, timing can be difficult, particularly in an acute care setting, because the focus is on an early discharge. By the time the patient is ready to learn, discharge may already be scheduled. Therefore, you need to anticipate a patient's educational needs.

The length of teaching sessions also influences learning. Concentration decreases with prolonged sessions. You should assess a patient's level of concentration by observing nonverbal cues such as poor eye contact or slumped posture. Teaching sessions should be held often enough to document the patient's learning progress. The frequency of sessions depends on the learner's abilities and the complexity of the material. For example, a child in whom diabetes has been newly diagnosed will require more visits to an outpatient centre than will an older adult who has been managing diabetes for 15 years. Intervals between teaching sessions should not be so long that the patient might forget information.

Organizing Teaching Material

An outline helps organize information into a logical sequence. Material should progress from simple to complex. A person must learn simple facts and concepts before learning associations or complex concepts.

Essential content should be taught first because people are more likely to remember information that is taught early. Repetition reinforces learning. Summarizing key points helps the learner remember important information (Bastable, 2008).

Maintaining Attention and Promoting Participation

Active participation is key to learning. People learn better when more than one of the body's senses is stimulated. Nurses should engage the patients' interest by changing the tone and intensity of their voice, making eye contact, using gestures, asking questions, and encouraging participation with activities such as role playing.

► BOX 20-8 NURSING CARE PLAN

Learning Needs

Assessment

Connie, a nurse in a surgeon's office, is preparing Mr. Holland for a colon resection, which is scheduled in one week. Mr. Holland, aged

75, has recently received a diagnosis of colorectal cancer. Connie's assessment focuses on Mr. Holland's readiness to learn, available resources, and factors that might affect his ability to understand the procedure and related postoperative care.

Assessment Activities

Assess Mr. Holland's readiness to learn, and ask what the surgeon has already told him about the surgery.

Findings and Defining Characteristics

Mr. Holland responds, "I can't remember what the doctor told me at my last appointment. My surgery is scheduled for next week."

Ask Mr. Holland to explain postoperative care, including performing a return demonstration of deep breathing and coughing.

Mr. Holland is unable to describe postoperative care or provide a return demonstration of deep breathing and coughing.

Assess Mr. Holland's visual acuity.

Mr. Holland says he has difficulty reading small print.

Nursing Diagnosis: Deficient knowledge related to lack of recall and exposure to information

Planning

Goal (Nursing Outcomes Classification)*

Mr. Holland will describe preoperative and postoperative care to nurse before surgery.

Expected Outcomes*

Knowledge of Treatment Procedures

Mr. Holland will verbalize understanding of surgical procedure and related care on the day of surgery.

Mr. Holland will participate in postoperative care during hospitalization.

Mr. Holland will demonstrate deep breathing and coughing; he will advance his level of activity after his surgery.

*Outcome labels from Moorhead, S., Johnson, M., Maas, M. L., & Swanson, E. (Eds.). (2008). *Nursing outcomes classification (NOC)* (4th ed.). St Louis, MO: Mosby.

Interventions (Nursing Interventions Classification)[†]

Learning Readiness Enhancement

Determine readiness to learn and what the patient perceives as important to know.

Rationale

Adult patients' learning is enhanced when they are ready to learn and the information is perceived as important (Bastable, 2008).

Learning Facilitation

Give patient large-print brochure describing preoperative and postoperative care during educational session.

Providing patients with educational methods that use multiple senses is effective in educating older adults. Large fonts with contrasting colours are easier for older adults to visualize (Chubaty et al., 2009).

Provide patient with Internet address associated with clinic to access patient information and instructional video clips.

Explain postoperative care, demonstrate deep breathing and coughing, and have patient perform return demonstration.

Improving self-efficacy by using role modelling and by having the patient perform behaviours enhances the successful adoption of healthy behaviours (Bandura, 1997).

[†]Intervention classification labels from Bulechek, G. M., Butcher, H. K., & Dochterman, J. M., (Eds.). (2008). *Nursing interventions classification (NIC)* (5th ed.). St Louis, MO: Mosby.

Evaluation

Nursing Actions

Ask Mr. Holland what he can expect before and after surgery.

Patient Response and Finding

Mr. Holland is able to state understanding of preoperative and postoperative care.

Achievement of Outcome

Mr. Holland's anxiety level has decreased, and he reports that he is ready for surgery.

Observe patient as he demonstrates deep breathing and coughing and advances his activity postoperatively.

Mr. Holland is able to cough and breathe deeply postoperatively, but he is hesitant to advance his activity level after surgery.

Outcome of advancing activity postoperatively has not been totally achieved. Address and manage barriers inhibiting attainment of this outcome (e.g., pain), and continue to encourage and educate patient.

Building on Existing Knowledge

An effective teacher presents information that builds on a learner's existing knowledge. For example, a patient who has had multiple sclerosis must begin a new medication that is given subcutaneously. On assessment, you ask the patient

about experience with injections. The patient explains that she gave her father insulin injections for many years. You then individualize the teaching plan by building on the patient's previous knowledge and experience with insulin injections.

Selecting Teaching Methods

A teaching method is the way that the teacher delivers information. It is based on the patient's learning needs. More than one method may be used for instruction. For example, a patient who learns best in the psychomotor domain will benefit from demonstrations and supervised practice. The patient masters skills by manipulating equipment and practising manual skills. Discussions, question-and-answer sessions, and formal lectures can all be effective methods, depending on the patient's needs and learning style. When choosing appropriate teaching methods, you should encourage the patient to offer suggestions (Box 20-9).

Selecting Resources

You are responsible for ensuring that patients' educational needs are met. Sometimes patients' needs are highly complex.

BOX 20-9 PATIENT TEACHING

Teaching Strategies

- Establish trust with the patient before beginning the teaching-learning session.
- Limit teaching objectives.
- Use simple terminology to enhance the patient's understanding.
- Avoid medical jargon. If necessary, explain medical terms by using basic one- or two-syllable words.
- Schedule short teaching sessions at frequent intervals; minimize distractions during teaching sessions.
- Begin and end each teaching session with the most important information.
- Present information slowly, pacing to provide ample time for the patient to understand the material.
- Repeat important information.
- Provide many examples that have meaning to the patient; for example, relate new material to a previous life experience.
- Build on existing knowledge.
- Use visual cues and simple analogies when appropriate.
- Ask the patient for frequent feedback to determine whether the patient comprehends information.
- Demonstrate procedures such as measuring dosages; ask for return demonstrations (which provide opportunities to clarify instructions and time to review procedures).
- Provide teaching materials that reflect the reading level of the patient; use material that is written with short words and sentences, large type, and simple format (in general, information written on a Grade 5 reading level is recommended for adult learners).
- Provide teaching materials that reflect health literacy of the patient; use material that avoids jargon, acronyms, and unnecessary medical terminology and defines medical terms that are necessary.
- Model appropriate behaviour and use role playing to help patient learn how to ask questions and ask for help effectively.
- Pace the delivery of material so that patients can progress at their own speed.
- Include family members or other caregivers in the education process.

In these cases, you identify appropriate health education resources within the health care system or the community. Examples of resources for patient education are diabetes education clinics, cardiac rehabilitation programs, prenatal classes, and support groups. You obtain a referral if necessary, encourage patients to attend these sessions, and reinforce information taught.

Writing Teaching Plans

In all health care settings, nurses develop written teaching plans for use by colleagues. The nurse responsible for developing the teaching plan incorporates all pertinent information into the plan, including topics for instruction, resources (e.g., equipment, teaching booklets, and referrals to education programs), recommendations for involving family, and objectives of the teaching plan. A plan may be detailed or in outline form.

In an acute care setting, plans are concise and focused on the primary learning needs of the patient because time for teaching is limited. A home care teaching plan or outpatient clinic plan may be more comprehensive because nurses may have more time to instruct patients, and patients are often less anxious in outpatient settings.

A plan should provide continuity of instruction, particularly when several nurses are involved in a patient's care. The more specific the plan is, the easier it is to follow.

Implementation

Implementing a teaching plan depends on your ability to analyze assessment data when identifying learning needs and developing the teaching plan (see Box 20-8). You evaluate the learning objectives and determine the best teaching and learning methods to help the patient to meet expected goals and outcomes. You use a diversified approach to create an active learning environment (Box 20-10).

Teaching Approaches

A teaching approach is different from a method. Because a learner's needs and motives can change over time, you must be ready to modify teaching approaches.

Telling. The telling approach is useful when limited information must be taught (e.g., preparing a patient for an emergency diagnostic procedure). You outline the task to be done and the patient's role and give instructions—for example, explaining the insertion of an IV and the need for the patient to remain still. This method provides no opportunity for feedback.

Selling. The selling approach entails two-way communication. You pace instruction according to the patient's response. Specific feedback is given to the patient who learns successfully. For example, when the patient learns a step-by-step procedure for changing a dressing, first the patient learns to remove the old dressing, then to clean the wound, and finally to apply a new dressing.

Participating. Participating involves setting objectives and becoming involved in the learning process together. The patient helps decide content, and you guide and counsel the patient with pertinent information. Opportunities are provided for discussion, feedback, mutual goal setting, and revision of the teaching plan. For example, a patient's request for information about improving physical fitness leads to a discussion with the patient in which you identify key areas of interest, such as weight loss and improving cardiovascular fitness.

Data from Bastable, S. (2008). *Nurse as educator: Principles of teaching and learning for nursing practice*. Sudbury, MA: Jones & Bartlett; Lowenstein, A. J., Foord-May, L., & Romano, J. C. (Eds.). (2009). *Teaching strategies for health education and health promotion: Working with patients, families and communities*. Sudbury, MA: Jones & Bartlett.

► BOX 20-10

**Example of Nursing Interventions
Based on Patient's Learning Needs****Assessment Data**

Mr. Kennedy, aged 67, has a 15-year history of type 2 diabetes. He is in the hospital because of an infected foot ulcer that necessitates frequent dressing changes. Mr. Kennedy used to take oral hypoglycemic agents to control his blood glucose levels. However, he now needs to start home insulin injections because of the infection and wound. He must also learn how to change his dressings. Mr. Kennedy is anxious about his discharge and requests information about a local diabetes support group and Internet resources. The case manager indicates that Mr. Kennedy will be discharged soon.

Cognitive Interventions

- Ask Mr. Kennedy about what he believes he needs to know before his discharge.
- Encourage Mr. Kennedy to help establish learning outcomes and goals.
- Provide Mr. Kennedy with teaching materials regarding insulin preparation, administration, and how to recognize and manage hypoglycemia and hyperglycemia.
- During teaching sessions, give Mr. Kennedy examples of what problems he might experience at home and ask him how he would respond to the situations (e.g., "If the wound's drainage increases and it looks like there is pus, what would you do?").
- Provide Mr. Kennedy with the Web address for the Canadian Diabetes Association.

Affective Interventions

- Encourage Mr. Kennedy to attend a support group meeting if possible to facilitate learning from others' experiences.
- Encourage Mr. Kennedy to verbalize his feelings and fears about this change in his health status.
- Have Mr. Kennedy role play how he will respond to his friends when they ask him about his health status.
- As he acquires new skills and behaviours, provide Mr. Kennedy with feedback and positive reinforcement.

Psychomotor Interventions

- Demonstrate insulin preparation and injection techniques.
- Demonstrate use of blood glucose meter and recording of blood glucose measurements.
- Demonstrate dressing changes.
- Ask Mr. Kennedy to perform return demonstrations of insulin preparation and injection, blood glucose testing, and dressing changes.

Figure 20-2 Using the administration of medication to assess a patient's knowledge about medications and provide additional information as needed.

desired behaviour is likely to repeat the behaviour. People usually respond better to positive reinforcement (Bastable, 2008). The effects of negative reinforcement, such as criticizing, can decrease an undesired response but are less predictable and often undesirable. Feedback is a common form of reinforcement.

Three types of reinforcers are social, material, and activity. Most nurses use social reinforcers (e.g., encouraging words) to acknowledge a learned behaviour. Examples of material reinforcers are food, toys, and music. These reinforcers work best with young children. Activity reinforcers are based on the principle that people are motivated to engage in an activity if after its completion they are able to engage in a more desirable activity. For example, patients with dementia may be more willing to bathe if they can go for a walk with you afterward. Activity reinforcers work when a patient is self-motivated. Choosing an appropriate reinforcer requires attention to individual preferences. Observing behaviour often helps reveal the best reinforcer to use. Reinforcers should never be used as threats and are not effective with every patient.

Incorporating Teaching Into Nursing Care

Many nurses teach effectively while delivering nursing care. This activity becomes easier as you gain confidence in clinical skills. For example, while hanging a blood bag, you explain why the blood is needed, and you describe the symptoms of transfusion reactions that should be reported immediately. When you follow a teaching plan informally, the patient feels less pressure to perform, and learning becomes more of a shared activity. Teaching during routine care is efficient and cost-effective (Figure 20-2).

Together with the patient, you identify goals and learning strategies.

Entrusting. The entrusting approach provides the patient with the opportunity to manage self-care. You observe the patient's progress and remain available to assist without introducing more new information. For example, a patient with metabolic syndrome has decided to make lifestyle changes (e.g., improve diet and exercise) to improve his or her health. You provide resources and recommend other sources of information. You meet with the patient on a regular basis to check progress and provide additional information.

Reinforcing. Reinforcement is the use of a stimulus that increases the probability of a response. A person who receives positive reinforcement before or after learning a

Implementing Teaching Methods

Your choice of teaching methods depends on the patient's learning needs, the time available for teaching, the environment, the resources, and the nurse's own comfort level with teaching. Skilled teachers are flexible in altering teaching methods according to the learner's responses and in using teaching tools that work best with a particular method. Various teaching tools are detailed in Table 20-2.

One-on-One Discussion. In one-on-one discussion, you present information informally, providing the patient with the opportunity to ask questions or share concerns. During the discussion, you can use various teaching aids such as models or diagrams, depending on the patient's learning needs.

Group Instruction. Groups are an economical way to teach several patients at once. Patients interact and learn from other's experiences. Groups can also foster positive attitudes that help patients meet learning objectives (Rankin & Stallings, 2005).

Group instruction often involves both lecture and discussion. Lectures are highly structured and help patients learn standard content. However, they do not encourage active thinking; thus, discussion and practice sessions are essential (Rankin & Stallings, 2005).

Preparatory Instruction. Patients are often anxious about unfamiliar tests or procedures. By providing information about procedures, you help patients anticipate what will

► TABLE 20-2 Teaching Tools for Instruction

Description of Tool

Printed Material

Written teaching tools such as pamphlets, booklets, and brochures

Implications for Learning

Material must be easily readable for learner.
Information must be accurate and current.
Method is ideal for understanding complex concepts and relationships.

Programmed Instruction

Written sequential presentation of learning steps requiring that learners answer questions and that teachers tell them whether their answers are right or wrong

Instruction is primarily verbal, but teacher may use pictures or diagrams.
Method requires active learning, giving immediate feedback, correcting wrong answers, and reinforcing right answers.
Learner works at own pace.

Computer Resources

Computer Programs

Programmed instruction format in which computers store response patterns for learners and select further lessons on basis of these patterns (programs can be individualized)

Method requires reading comprehension, psychomotor skills, and familiarity with computer.

Internet Resources

Provides access to instructional resources which might not be available locally and which may be interactive and include demonstrations, video clips, self-directed modules, Web-based learning

Method requires access to the Internet, psychomotor skills, and familiarity with computer.

Audiovisual Materials

Diagrams

Illustrations that show interrelationships by means of lines and symbols

Method demonstrates key ideas and summarizes and clarifies key concept.

Graphs (Bar, Circle, or Line)

Visual presentations of numerical data

Graphs help learner to grasp information quickly about single concept.

Charts

Highly condensed visual summaries of ideas and facts that may highlight series of ideas, steps, or events

Charts demonstrate relationship of several ideas or concepts.
Method helps learners know what to do.

Pictures

Photographs or drawings used to teach concepts in which the third dimension of shape and space is not important

Photographs are more desirable than diagrams because they more accurately portray the details of the real item.
Drawings are pertinent for removing the superfluous detail present in real objects.

Physical Objects

Use of actual equipment, objects, models or simulation to teach concepts or skills

Models are useful when real objects are too small, large, or complicated or are unavailable.
Learners can manipulate objects that are to be used later in skill.

Other Audiovisual Materials

Slides, audiotapes, television, and videotapes used with printed material or discussion

Materials are useful for patients with reading comprehension problems and visual deficits.

happen. Guidelines for giving preparatory explanations are as follows:

- Describe physical sensations during the procedure, but do not evaluate them. For example, when you draw a blood specimen, explain that the patient will feel a sticking sensation as the needle punctures the skin.
- Describe the cause of the sensation to prevent misinterpretation of the experience. For example, explain that a needle stick burns because the alcohol used to cleanse the skin enters the puncture site.
- Prepare patients only for aspects of the experience that are common to other patients. For example, explain that it is normal for a tight tourniquet to cause a person's hand to tingle and feel numb.

Demonstrations. Demonstrations help teach psychomotor skills such as preparing a syringe, bathing an infant, walking with a crutch, or measuring a pulse. Patients are able to observe a skill before practising it. Demonstrations are most effective when patients first observe you and then perform a **return demonstration** to practise the skill. A demonstration should be combined with discussion to clarify concepts and feelings. An effective demonstration requires advanced planning:

- Position the patient to provide a clear view of the demonstration.
- Review the rationale and steps of the procedure.
- Assemble and organize equipment. Make sure it works.
- Perform each step in sequence while analyzing the knowledge and skills involved.
- Determine when to give explanations, considering the patient's learning needs.
- Adjust speed and timing of the demonstration according to the patient's abilities and anxiety level.

You demonstrate the steps of a procedure in the same order in which the patient will perform them. The demonstration involves the following:

- Performing each step slowly and accurately
- Encouraging the patient to ask questions so that each step is understood
- Explaining the rationale for each step
- Allowing the patient to observe each step
- Providing the patient with the opportunity to handle equipment and practise the procedure under supervision

The patient demonstrates the procedure to ensure that learning has occurred. The demonstration should occur under the same conditions that will be experienced at home or in the place where the procedure is to be performed. For example, for a patient learning to walk with crutches, you simulate the home environment. If short, narrow steps lead to the patient's bedroom, the patient should learn to climb similar stairs in the hospital.

Analogies. Learning occurs when a teacher translates complex language or ideas into words or concepts that the patient understands. **Analogies** aid learning by supplementing verbal instruction with familiar images that make complex information simpler and understandable. For example, to explain arterial blood pressure, an analogy is the flow of water through a hose. To use analogies, follow these general principles:

- Be familiar with the concept.
- Know the patient's background, experience, and culture.
- Keep the analogy simple and clear.

Role Playing. Role playing helps teach new ideas and attitudes. During role playing, patients play themselves or

someone else and rehearse a desired behaviour. For example, you can teach a parent to respond to a child's behaviour by pretending to be a child having a temper tantrum. This role playing provides the parent with the opportunity to practise responding in this situation. You evaluate the parent's response and determine whether an alternative approach would be more appropriate. Role playing helps patients learn skills and feel confident in their ability to perform them independently.

Simulation. Simulation helps teach problem solving, application, and independent thinking. During individual or group discussion, a nurse poses a problem or situation for patients to solve. For example, patients with heart disease are asked to plan a low-fat meal. You ask the patients to present their diet, providing an opportunity to identify mistakes and reinforce correct information.

Paying Attention to Learning Barriers. Many situations or conditions present a barrier to learning. For example, the patient may have a low reading level (functionally illiterate), a learning disability, a sensory alteration, or depression; may be suffering the effects of prescribed medications or adjusting to life changes or transitions; or may have a poor memory. Patients understand fewer medical words than health care providers predict. Unfortunately, health care providers often use medical terminology and jargon, which prevents patients from understanding the written health information they are given (Sand-Jecklin, 2007). Professionals should pay special attention to the learning needs of patients who have reading problems, learning disabilities, and sensory alterations and of those whose first language is not English or French.

Illiteracy and Learning Disabilities. A 2005 survey on literacy rates in Canada (Statistics Canada & Organisation for Economic Cooperation and Development, 2005) revealed that about 15% of Canadian adults fall within the lowest level of literacy. These people have only rudimentary reading and writing skills; for example, they are not able to read and understand a label on a medicine container. An additional 27% of Canadians can read only material that is simple and familiar. Therefore, almost half of Canadians have problems with reading materials encountered in everyday life. To compound this problem, the readability of printed material ranges from elementary school level to college level. Researchers have found that printed educational material is consistently written above most patients' reading level (Cutilli, 2005; Demir et al., 2008). Health care providers need to screen materials for readability and clarity.

Some people have learning disabilities, which are disorders that may impair ability to acquire, organize, remember, understand, or apply information (Learning Disabilities Association of Canada, 2002). The ability to learn or use oral or written language, mathematics, or both may be poor. Teaching strategies need to be adapted to accommodate their learning needs. For example, patients with attention deficit-hyperactivity disorder may have difficulty recalling information and staying focused during educational sessions; they may also have a low threshold of frustration (Bastable, 2008). Teaching activities should be kept short in an environment with minimal competing stimuli.

Health Literacy. Health literacy refers to a patient's ability to find, access, read, and understand reliable health information and to use that information to make informed decisions about their health. Many patients have difficulty accessing and understanding health information (Squellati,

2010). Aspects of health literacy of particular note are the ability to identify and access reliable information. Patients no longer depend solely on their health care provider. They are bombarded with health related advertisements and may seek information on the Internet, some of which is incomplete or inaccurate. They can be either well-informed about their health or misinformed about their health, depending on their health literacy. Patient information needs to be presented clearly, avoiding medical terminology, jargon, and acronyms that the patient may not be familiar with.

Sensory Alteration and Other Barriers. Some patients, including many older adults, have sensory deficits (see Chapter 47). Sensory changes such as visual and hearing deficits necessitate teaching methods that enhance functioning. For example, you face a patient with hearing problems and speak in a low tone of voice during discussions (lower tones are easier to hear than are higher tones). Clearly written materials should be provided. Patients with visual problems can benefit from large-print materials. Patients with slower cognitive function and reduced short-term memory (such as some older adults and patients who have had strokes) learn and remember effectively if the learning is paced properly and the material is relevant to the learner's needs and abilities.

Language

The diverse backgrounds of Canadians can challenge you to provide culturally sensitive care (see Chapter 9). Patients may not understand instructions that are not in their native language (see Chapter 17). You need to ascertain a patient's

fluency in English or French before you choose teaching methods or tools.

Cultural Diversity

You need to have knowledge of patients' cultural background, values, and beliefs (see Chapter 9), as well as the patient's ability to understand both verbal and written material (Cutilli, 2006). When educating patients of cultural groups different from your own, you need to be aware of the distinctive aspects of their cultures and develop teaching strategies that are respectful of cultural beliefs, values, and behaviours.

Needs of Patients With Severe Illness

Adapting to serious illness or disability is difficult for most people. They need to grieve. The grieving process gives them time to adapt psychologically to the emotional and physical implications of illness. People experience grief (see Chapter 28) at different rates and sequences, depending on their self-concept before illness, the severity of the illness, and the changes and losses caused by the illness. Sensitivity is required to educate patients while they are grieving and adjusting to their illness.

Readiness to learn is related to the grieving stage (Table 20-3). Patients cannot learn when they are unwilling or unable to accept the reality of illness. However, properly timed teaching can help a patient to adjust to illness or disability. You must identify the patient's stage of grieving on the basis of the patient's behaviours. When the patient enters the stage of acceptance, the stage compatible with learning, you can

► **TABLE 20-3 Relationship Between Learning and Psychosocial Adaptation to Illness**

Stage	Patient's Behaviour	Nursing Activities	Rationale
Denial or disbelief	Patient avoids discussion of illness ("Nothing is wrong with me"), withdraws from others, and disregards physical restrictions. Patient suppresses and distorts information that has not been presented clearly.	Provide support, empathy, and careful explanations of all procedures while they are being done. Let patient know you are available for conversation. Explain situation to family or significant other if appropriate. Teach in present tense (e.g., explain what patient needs to know to be discharged).	Patient is not prepared to deal with problem; attempts to teach patient will result in further anger or withdrawal. Provide only information that patient pursues or requires.
Anger	Patient blames, complains, and often directs anger toward nurse or others.	Do not argue with patient, but listen to concerns. Teach in present tense. Reassure family of the normality of patient's behaviour.	Patient needs opportunity to express feelings and anger. Patient is still not prepared to face future.
Bargaining	Patient offers to live better life in exchange for promise of better health (e.g., "If God lets me live, I promise to manage my disease better").	Continue to introduce only reality and teaching in present tense.	Patient is still unwilling to accept limitations.
Resolution	Patient begins to express emotions openly, realizes that illness has created changes, and begins to ask questions.	Encourage expression of feelings. Begin to share information needed for future, and set aside formal times for discussion.	Patient begins to perceive need for assistance and is ready to accept responsibility for learning.
Acceptance	Patient recognizes reality of condition, actively pursues information, and strives for independence.	Focus on future skills and knowledge required. Continue to teach in present tense. Involve family in planning and teaching for discharge.	Patient is more easily motivated to learn. Acceptance of illness reflects willingness to deal with its implications.

introduce a teaching plan. Continuous assessment of the patient's behaviours determines the stages of grieving.

❖ Evaluation

Patient education is not complete until you evaluate outcomes of the teaching-learning process (see Box 20-8). You must determine whether patients have learned the material. Evaluation reinforces correct behaviour, helps learners realize how they should change incorrect behaviour, and helps you determine the adequacy of the teaching (Redman, 2007). Success depends on the patient's ability to meet the established outcome and goals by which you can evaluate success. The following checklist helps evaluate patient education (Rankin & Stallings, 2005):

- Were the objectives clearly stated in a way that allowed patient behaviours to be observed?
- Were the patient's goals or outcomes realistic?
- Were the learner's needs assessed thoroughly?
- Did the patient perceive the education as important, and did the patient state a willingness to change behaviour?
- What obstacles or problems were encountered that provided barriers to change?
- Were educational goals set mutually between the nurse and the patient?
- Were the interventions individualized to help the patient meet the learning objectives?
- Was the patient's behavioural change measured and documented accurately?
- Does the patient continue to have a skill deficiency? If so, what changes in interventions should be made to enhance skill attainment?
- Does any follow-up or reassessment need to be performed?

Measurement Methods

Under direct observation, the patient should demonstrate the behaviours described in the learning objectives. If the evaluation process indicates a deficit in knowledge or skill, you must repeat or modify the teaching plan. By watching patients demonstrate behaviours, you can see whether correct techniques are used. However, a patient may behave differently later. Therefore, observation works best in real-life situations.

Oral and written questioning are other useful evaluation methods. Questions are best used for behaviours that are not easily demonstrated. You should phrase questions to ensure that the learner understands them and that objectives are truly measured.

Another form of evaluation includes self-reports (oral and written) and self-monitoring (written). An example is a patient's written log of the foods eaten in a specific time period, in comparison with a new diet. You rely on the patient's honesty and memory in self-reporting.

Patient Expectations

Evaluations of nursing care and teaching sessions help determine whether a patient's needs and expectations have been met. At the end of the session, you ask the patient whether he or she has questions; in this way, you can identify information that was missing and should have been covered. Patients may also fill out written evaluations of a teaching session or course. Anonymous written evaluations may be more truthful than are face-to-face evaluations.

Evaluation may reveal new learning needs or new factors that are interfering with learning, in which case you should try alternative teaching methods. When a patient has difficulty in an acute care setting, you may make a referral to resources, such as home care or an outpatient clinic, for further education and evaluation.

Documentation

Because patient teaching often occurs informally, it is difficult to document it consistently. You are legally responsible for providing accurate, timely information that promotes continuity of care; therefore, it is essential to document the outcomes of teaching. Rankin and Stallings (2005) suggested documenting the following with regard to patient education:

- *Assessment data and reassessment of learning needs.* Such data and evaluation provide important information needed when the teaching plan is developed.
- *Nursing diagnoses, patient needs, and educational priorities.* These provide support for goals and outcomes that are established.
- *Interventions planned.* A specific plan, including the methods to be used in instruction, enhances continuity of care. When viewing the planned interventions, you can determine what information needs to be provided to the patient.
- *Interventions provided.* Specifically describing the subject matter enables other nurses to follow up and reinforce teaching (e.g., "Explained side effects of Inderal" or "Demonstrated umbilical cord care"). Note the date, time, and specific patient or patients taught. Avoid generalizations (e.g., "medications taught"). Resources used, such as pamphlets or audiovisual materials, are documented in the patient's record.
- *Patient's response and outcomes of care.* In documenting evidence of learning (e.g., a return demonstration or the ability to verbalize the purpose and side effects of a medication), you inform staff about the patient's progress and determine information that must still be taught.
- *Ability of patient, family, or both to manage needs after discharge.* An evaluation of remaining educational needs on discharge helps identify the need for outpatient or home health care follow-up. If referrals are appropriate, the patient, family, or both are often able to meet their needs.

❖ KEY CONCEPTS

- The nurse ensures that patients, families, and communities receive information needed to maintain optimal health.
- Health education is aimed at the promotion, restoration, and maintenance of health.
- Teaching is most effective when it is responsive to the learner's needs.
- Teaching is a form of interpersonal communication, with the teacher and student actively involved in a process that increases the student's knowledge and skills.
- The ability to learn depends on a person's physical and cognitive attributes.
- The ability to attend to the learning process depends on physical comfort and anxiety levels and on the presence of environmental distraction.
- A person's health beliefs influence the willingness to gain knowledge and skills necessary to maintain health.
- Teaching must be timed to coincide with the patient's readiness to learn.

- Patients of different age groups require different teaching strategies as a result of developmental capabilities.
 - The patient should be an active participant in a teaching plan: agreeing to the plan, helping choose instructional methods, and recommending times for instruction.
 - Learning objectives describe what a person is to learn in behavioural terms.
 - A combination of teaching methods improves the learner's attentiveness and involvement.
 - A teacher is more effective when presenting information that builds on a learner's existing knowledge.
 - Nurses should assess which learning materials, methods, and approaches will be most effective for each patient, on the basis of each patient's individual abilities and challenges.
 - A nurse evaluates a patient's learning by observing performance of expected learning behaviours under desired conditions.
 - Effective documentation describes the entire process of patient education, promotes continuity of care, and demonstrates that educational standards have been met.
2. You should plan to teach a patient about the importance of exercise
 1. When visitors are in the room
 2. When the patient's pain medications are effectively managing pain
 3. Just before lunch, when the patient is most awake and alert
 4. When the patient is talking about current stressors in his or her life
 3. A patient with newly diagnosed cervical cancer is going home. The patient is avoiding discussion of her illness and postoperative orders. In teaching the patient about discharge instructions, you should
 1. Teach the patient's spouse
 2. Focus on knowledge the patient will need in a few weeks
 3. Provide only the information the patient needs to go home
 4. Convince the patient that learning about her health is necessary

❖ CRITICAL THINKING EXERCISES

1. Mrs. S. has a 10-year history of hypertension and a 5-year history of diabetes. Recently, her hypertension has worsened and she has received a diagnosis of depression. Her medications, which have recently been changed, include 25 mg of captopril (Capoten) three times a day; 240 mg of diltiazem (Cardizem CD) every morning; 1500 mg of metformin (Glucophage XR) before the evening meal; and 100 mg of sertraline (Zoloft) by mouth at bed time. You identify the priority nursing diagnosis as *deficient knowledge related to change in medications*. You want to develop a plan of care in which the three domains of learning are used. What are the patient's teaching priorities? Which learning needs would necessitate a cognitive method? Which needs would be more appropriate to satisfy through affective or psychomotor methods?
 2. You are caring for a patient who is being discharged after an appendectomy. He takes medication to treat attention deficit-hyperactivity disorder. Which teaching strategies should you use when providing discharge information to this patient?
 3. A 23-year-old man has recently sustained a spinal cord injury after being involved in a diving accident that has left him paralyzed from the waist down. He verbally abuses the staff and expresses anger toward his family and friends when they come to visit. He needs to begin learning transfer techniques. Which stage of grieving is this patient experiencing? What approach should you take in planning education for this patient?
 4. A 65-year-old woman is taking her 72-year-old husband home after surgery. Which strategies should you use in helping this couple make the transition to home smoothly?
4. You are a community health nurse about to teach a Grade 12 health class about nutrition. To achieve the best learning outcomes, you should
 1. Provide information by using a lecture
 2. Use simple words to promote understanding
 3. Complete an extensive literature search focusing on eating disorders
 4. Develop topics for discussion that necessitate problem solving
 5. You are going to teach a patient how to perform a breast self-examination. The behavioural objective that would best measure the patient's ability to perform the examination is as follows:
 1. The patient will verbalize the steps involved in breast self-examination within one week.
 2. You will explain the importance of performing breast self-examination once a month.
 3. The patient will perform breast self-examination correctly before the end of the teaching session.
 4. You will demonstrate breast self-examination on a breast model provided by the Canadian Cancer Society.
 6. A patient who is having chest pain is about to undergo an emergency cardiac catheterization. Which of the following is the most appropriate teaching approach in this situation?
 1. Telling
 2. Selling
 3. Entrusting
 4. Participating

❖ REVIEW QUESTIONS

1. A patient must learn to use a walker. Acquisition of this skill will require learning in which domain?
 1. Cognitive
 2. Affective
 3. Psychomotor
 4. Attentional
7. You are teaching a parenting class to a group of pregnant adolescents and have given the adolescents baby dolls to bathe and talk to. This is an example of
 1. Discovery
 2. An analogy
 3. Role playing
 4. A demonstration

8. A patient with a learning disability is starting to take a new antihypertensive medication. In teaching the patient about the medication, you should
 1. Demonstrate measuring dosages and ask for a return demonstration
 2. Provide only written material
 3. Present the information once
 4. Expect the patient to understand the information quickly
9. A patient must learn how to administer a subcutaneous injection. You know the patient is ready to learn when the patient
 1. Has been given written instructions
 2. Expresses the importance of learning the skill
 3. Can see and understand the markings on the syringe
 4. Has the dexterity needed to prepare and inject the medication
10. A patient who is hospitalized has just received a diagnosis of diabetes. He needs to learn how to give himself injections. The best teaching method would be
 1. Demonstration
 2. Group instruction
 3. One-on-one discussion
 4. Simulation

❖ RECOMMENDED WEB SITES

Public Health Agency of Canada: <http://www.phac-aspc.gc.ca/index-eng.php>

This Web site provides information and resources on a variety of public health issues and topics, including health promotion, healthy living, diseases, and injury prevention.

Health Canada: <http://www.hc-sc.gc.ca>

This Web site provides many resources on a variety of health issues and topics to assist in patient education:

Canadian Public Health Association: <http://www.cpha.ca/en/default.aspx>

This Web site provides both national and international information and resources on public health issues and services.

National Institutes of Health: <http://health.nih.gov/>

Prepared by the National Institutes of Health in the United States, this Web site provides a great many resources for patient education.

Developmental Theories

Original chapter by Karen Balakas, RN, PhD, CNE

Canadian content written by Nicole Letourneau, RN, PhD

objectives

Mastery of content in this chapter will enable you to:

- Define the key terms listed.
- Identify basic principles of growth and development.
- Discuss factors influencing growth and development.
- Identify five major traditions that underlie modern developmental theories.
- Name and describe the major developmental theories associated with each tradition.
- Describe and compare the mechanisms that underlie the major developmental theories.
- Discuss nursing implications associated with the application of developmental principles to patient care.

All people progress through phases of growth and development, from the simple to the complex, at a highly individualized rate. Understanding typical growth and development helps nurses to predict, prevent, and detect any changes from patients' expected patterns and to develop approaches and programs that can further enhance the developmental well-being of individuals (Berk, 2006; Bukatko & Daehler, 2004). Understanding the impact of early experience on development in adulthood provides the foundation for nurses to advocate for appropriate developmental care for vulnerable children and families (McCain et al., 2007). Developmental theories also help nurses to assess and treat a patient's response to an illness. Understanding the process of human development helps caregivers to plan appropriate individualized care for patients (Berk, 2008; Edelman & Mandle, 2006).

For many years, human growth and development have been described as orderly, predictable processes beginning with conception and continuing until death. This view is increasingly being recognized as overlooking differences in gender, culture, and sexuality. Today, it is no longer assumed that all people progress through universal linear phases of growth and development. Human growth and development are now seen as processes in which sociocultural, biological, and psychological forces interact with the individual over time (Berk, 2008). As a result, theorists have changed focus from describing growth and development to explaining it. How do humans develop? What are the mechanisms, or explanatory components, that underlie human growth and development?

In this chapter, five broad traditions of human development are introduced, and the mechanisms of development espoused by key theorists are outlined. Examples of implications for the nursing process that follow from the mechanisms are offered. Detailed descriptions of human development appear in Chapters 22, 23, and 24.

Growth and Development

Growth and development are synchronous processes that are interdependent in the healthy individual. Growth and development depend on a sequence of endocrine, genetic, constitutional, environmental, and nutritional influences (Edelman & Mandle, 2006).

Physical Growth

Growth is the quantitative, or measurable, aspect of an individual's increase in physical measurements. Measurable growth indicators include changes in height, weight, teeth, skeletal structures, and sexual characteristics. For example, children generally double their birth weight by 5 months of age and their birth height by 36 months. Physical growth is not only genetic but is also affected by other contextual factors such as socioeconomic status.

Development

Development is a progressive and continuous process of change leading to increased skill and capacity to function. Development is the result of complex interactions between biological and environmental influences (Salkind, 2004). These changes are qualitative in nature and difficult to measure in exact units. Developmental changes have certain predictable characteristics: they proceed from simple to complex, from general to specific, from head to toe (cephalocaudal), and from the trunk to the extremities (proximodistal). For example, a

child's progressions from rolling over to crawling to walking are developmental changes.

Factors Influencing Growth and Development

Three major categories of factors influence human growth and development: (1) genetic or natural forces within the person, (2) the environment in which the person lives, and (3) the interaction that takes place between these two factors (Table 21-1). You apply knowledge of these factors when selecting approaches to promote typical growth and developmental progression. It is important, for example, that as part of planning for a patient's pregnancy, you consider the patient's genetic endowment, age, socioeconomic status, culture (Box 21-1), available support system, and preconceived state of health.

Traditions of Developmental Theories

A theory is an organized, often observable, logical set of statements about a subject. Human developmental theories are models intended to account for how and why people develop as they do (Thomas, 1997). All of the theories of development discussed in this chapter make different contributions to our understanding of the developmental process.

To help you understand the number of developmental theories, this chapter has been grouped into five traditions of (or ways of thinking about) theory development: organicism, psychoanalytic and psychosocial, mechanistic, contextualism, and dialecticism. The areas of learning and spiritual development are covered in Chapters 20 and 27, respectively.

Each tradition of developmental theory emphasizes different underlying developmental mechanisms. **Mechanisms of development** are the explanatory components of each theory, or the means by which the developmental tasks are achieved. They are the processes or factors that underlie the developmental process within each theory, and they enable developmental progression. These underlying mechanisms are proposed to be universal and to function across the lifespan, not just in childhood. Although developmental theories are often presented within a framework of stagelike progressions, what the stages actually represent are the outcomes produced by these mechanisms at each specific age.

► BOX 21-1

Cultural Aspects of Care: Canadian First Nations People

You need to assess the cultural background of each patient and be prepared to change your practice so that it is congruent with the patient's beliefs and values concerning growth and development. For example, within many Aboriginal cultures, the concept of a circle or cycle is a fundamental theme (Smylie, 2001) and can be applied to human development. Human states and concepts are considered to be part of the life cycle of the earth, which also includes plants, animals, and seasons (Smylie, 2000). For Aboriginal people, this life cycle may be described as a continuum of age-related roles and qualities of being, including physical, mental, emotional, and spiritual well-being. All aspects of human development are viewed as being in harmony with the cycle of life in nature. As in nature, each part of the cycle needs to be balanced with the other parts. Roles and expectations related to developmental age reflect traditional values of respect, honour, balance, and harmony. Figure 21-1 represents the circle of life, or the medicine wheel, as applied to the human life cycle.

► **TABLE 21-1** Major Factors That Influence Growth and Development

Categories	Implications
Genetic or Natural Factors	
Heredity	Genetic endowment determines sex, skin, hair and eye colour, physical growth, stature, and, to some extent, psychological uniqueness.
Temperament	Temperament is the characteristic psychological mood with which the child is born; it influences interactions between an individual and the environment.
Environmental Factors	
Family	Family purposes are to protect, teach, and nurture its members. Family functions include means for survival, security, assistance with emotional and social development, assistance with maintenance of relationships, instruction about society and world, and assistance in learning roles and behaviours.
Peer group	Family influences through its values, beliefs, customs, and specific patterns of interaction and communication. Peer group provides a new and different learning environment. Peer group provides different patterns and structures of interaction and communication, necessitating a different style of behaviour. Functions of peer group include allowing individual to learn about success and failure; to validate and challenge thoughts, feelings, and concepts; to receive acceptance, support, and rejection as a unique person apart from family; and to achieve group purposes by meeting demands, pressures, and expectations.
Health environment	Level of health affects an individual's responsiveness to environment and responsiveness of others to the individual.
Nutrition	It determines availability and accessibility of resources to support health. Growth is regulated by dietary factors. Adequacy of nutrients influences whether and how physiological needs, as well as subsequent growth and development needs, are met.
Rest, sleep, and exercise	The availability of quality nutrients also affects growth. Balance between rest, sleep, and exercise is essential for rejuvenating the body.
Living environment	Disturbances diminish growth, whereas equilibrium reinforces physiological and psychological health. Factors affecting growth and development include season, climate, community life, socioeconomic status, and quality of the physical environment (air, water, land). An embryo may be exposed to teratogenic substances (e.g., alcohol, chemicals, or radiation) that cause abnormal development.
Political and policy environment	Municipal, provincial, and federal policies directly affect the health and well-being of individuals, families, and communities.
Interacting Factors	
Life experiences	Individuals develop by applying what has been learned through experience to their current situation. Experiences emerge from both biological and environmental sources. The individual deduces meaning from these experiences and bases further actions on them.
Prenatal health	Biological and maturational factors (genetics; maternal age; medical problems) and environmental factors (maternal health; stress, nutrition; use of tobacco, drugs, and alcohol; use of prenatal services) together affect fetal growth and development.
State of health	Health is a product of both intrinsic (biology) and extrinsic (quality of environment, availability of resources for health) factors. Changes to health status such as illness or injury may cause inability to cope with and respond to underlying processes and demands of development.

Organicism

Organicism refers to a theoretical focus on the organism itself. According to theories in this tradition, development is a result of biologically driven behaviour and the person's adaptation to the environment. Biophysical and cognitive-moral theories of development are included in this tradition.

Biophysical Developmental Theories

Biophysical developmental theories describe and explain how the physical body grows and changes. The changes that occur as a person grows from fetus, to neonate, to child and

finally adult can be quantified and compared against established norms; however, regional and cultural differences may exist, as may differences related to the availability of resources in the environment for adequate growth.

How does the physical body age? What are the triggers that change the body's physical characteristics from childhood through adolescence to adulthood? Biological influences on development include many factors such as genetics and exposure to teratogens (e.g., maternal diseases, drugs, X-rays, or other hazardous substances that interfere with the normal development of the fetus). All biophysical developmental theories give some credence to the roles of nature (genetics) and

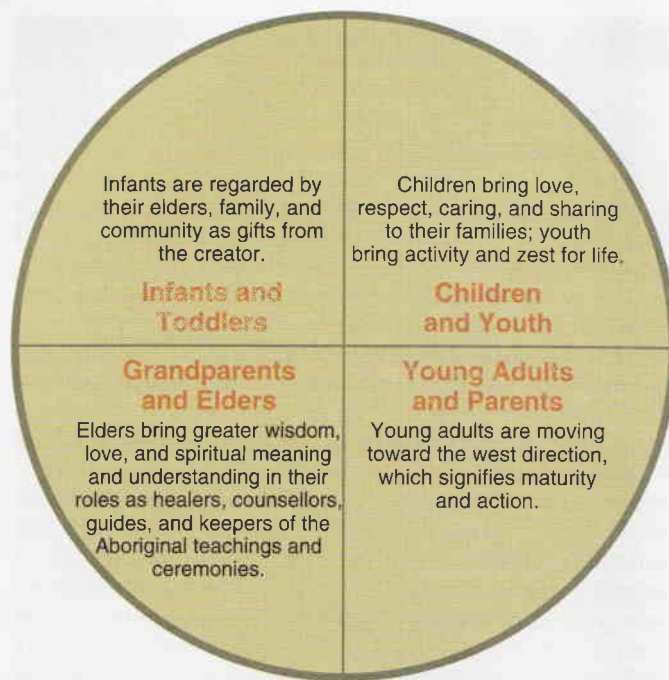

Figure 21-1 An Aboriginal perspective on human development: the circle of life, or the medicine wheel, as applied to the human life cycle. **Source:** Redrawn from Smylie, J. (2001, January). A guide for health professionals working with Aboriginal peoples: Health issues affecting Aboriginal peoples. *Journal SOGC*, 100, 55.

nurture (caregiving environment and resources). However, the theories differ sharply on how much influence individual and environmental forces have on development (Berk, 2006).

Gesell's Theory of Maturation Development.

Arnold Gesell (1880–1961) was a psychologist who obtained his medical degree to help him explain the physiological processes he observed in the behaviour of children. Through extensive observations in the 1940s, he developed behavioural norms that serve as a primary source of information for childhood development today.

Fundamental to Gesell's theory of development is the notion that the pattern of growth and development is directed by the activity of the genes, although at that time, the genetic mechanism was unknown to him. He believed that environmental factors can support, change, and modify the pattern but do not generate the progressions of development (Gesell, 1948). Gesell proposed that the pattern of maturation follows a fixed developmental sequence in all humans and that critical periods exist in which the presence or absence of particular experiences makes a biological system functional or nonfunctional (Keating & Hertzman, 1999). For example, if a child's visual defect is not identified until the start of school, usual message pathways in the brain may not become fully developed, and long-term vision may be impaired (Cynader & Frost, 1999).

Sequential development is seen in fetuses, in which the order of development of the various organ systems is specific (Crain, 2005). After birth, children grow according to their genetic blueprint and gain skills in an orderly manner, but at each individual's own pace. For example, most children learn first how to hold a cup with digital grasp at about 15 months of age and later how to lift, drink from, and replace the cup at 21 months of age. Gesell clarified that not every child develops

those skills at exactly the same ages. He pointed out that the environment does play a part in the development of the child but that it does not have any part in the sequence of development. Gesell believed that children could not be pushed to develop faster than their own unique timetables permitted. He also proposed that the biological body determines behavioural development. Researchers continue to use Gesell's theories today, probing for gene–environment interactions in human development (Cicchetti, 2007).

Mechanisms of Maturation Development. **Maturation** is the biological internal regulatory mechanism that governs the emergence of all new skills and abilities that appear with advancing age (Nelson et al., 2006). Maturation involves an individual's biological ability, physiological condition, and desire to learn more mature behaviour. To mature, the individual may have to relinquish previous behaviour and learning, integrate new patterns into existing behaviour, or both. Maturation influences the sequence and timing of the changes associated with growth and development. For example, the child relinquishes crawling for walking because walking permits greater investigation of the environment and more learning. However, the child cannot walk until the biological ability and structures to perform the action (i.e., increased muscle cells and tone) have developed.

Differentiation is the process by which cells and structures become modified and refine their characteristics. Development of activities and functions progresses from simple to complex. Embryonic cells begin as vague and undifferentiated and develop into complex, highly diversified cells, tissues, and organs.

Nursing Implications of Maturation Development.

As a nurse, you consider maturational development in your care planning when you help mothers sequence play activities appropriate for learning of sitting, rolling, creeping, crawling, and walking. You consider sequential development of fetuses and critical periods when you counsel expectant mothers about environmental teratogens during the first trimester of pregnancy. You support development during critical periods when you develop early intervention programs for parents.

Chess and Thomas's Theory of Temperament Development. **Temperament** is a physical and emotional response style that affects a child's interactions with others (Hockenberry & Wilson, 2007). It is the way a person adjusts to life experiences, and it is thought to originate within the person's genetic makeup. A child's temperament influences how others respond to the child and to his or her needs. Knowledge of temperament helps parents to have a clearer perspective of their child and enables health care providers to guide them appropriately (Hockenberry & Wilson, 2007).

Psychiatrists Stella Chess (1914–2007) and Alexander Thomas (1915–2003) conducted a landmark 20-year longitudinal study of development that included children from a range of populations, including children of middle-income parents and intellectually disabled children of lower-income parents. The breadth of the data allowed them to look at the behaviour of people from childhood to early adulthood as they interacted with their environment. Their work defined the concept of temperament (Chess & Thomas, 1995), and they proposed that temperament is biologically derived.

Chess and Thomas (1995) described three common categories of temperament, but individual variation meant that approximately 30% of children cannot be classified in any of these groups:

- The *easy child* is easygoing and even-tempered, regular and predictable in his or her habits, and open-minded and adaptable to change. Mood expressions are mild to moderately intense and typically positive.
- The *difficult child* is highly active, irritable, and irregular in habits. Negative withdrawal from other people is typical, and the child requires a highly structured environment. He or she adapts slowly to new routines, new people, or new situations. Mood expressions are usually intense and primarily negative.
- The *slow-to-warm-up child* typically reacts negatively and with mild intensity to new stimuli. He or she adapts slowly with repeated contact unless pressured and responds with mild but passive resistance to novelty or changes in routine.

Mechanisms of Temperament Development. According to temperament theory, biologically derived temperament characteristics drive children's interaction with the environment. Chess and Thomas (1995) proposed that it is through "goodness of fit" between the individual and the immediate environment that human development is modulated. This proposal places significant responsibility for child development outcomes within the family. For instance, the difficult child who has trouble making the transition from one activity or environment to a new one functions best in a family that maintains routine and has a slow, easy attitude toward the introduction of change. The same child in a family that has few routines has much more difficulty moving from one activity (such as play) to the next activity (such as sleep). The first scenario is an example of "goodness of fit" between the temperament of the child and the family environment. However, recent research suggests that temperament may be a function of fetal exposures to, for example, excessive maternal stress hormones during pregnancy or birth complications (de Weerth et al., 2003; de Weerth & Buitelaar, 2007).

Nursing Implications of Temperament Development. Nurses can help families identify the unique characteristics of their infants and children. For instance, a parenting program called "Keys to Caregiving" (Sumner, 1995) that consists of professional self-educational videos and parent pamphlets assists nurses in helping new parents identify their infants' usual behaviour and communication styles. Keys to Caregiving teaches new parents about infant cues and behaviours that signify needs (e.g., hunger, desire for playful attention), infant states and how to modulate infant states (e.g., helping soothe a fussy baby), and optimal parenting practices that promote sensitive, nurturant relationships between caregivers and infants. This information helps families adapt their habits and routines to match their children's temperaments. You can also consider temperament styles when working with adults and families in teaching or support situations.

Cognitive Developmental Theories

Cognitive developmental theories focus on reasoning and thinking processes, including the changes in how people perform intellectual operations. These operations are related to the ways people learn to understand the world in which they live. Mental processes, including perceiving, reasoning, remembering, and believing, affect certain types of emotional behaviour. For example, a child will have a different emotional reaction to the death of a grandparent than to the death of an older sibling or a parent.

Unlike biophysical developmental theories, cognitive developmental theories emphasize that although the developmental

process originates with the person, it is greatly influenced by interactions between the person and the environment. Therefore, theories of cognitive development emphasize the active role that the individual plays in the developmental process. Cognitive theories are considered to be within the organicism tradition because development is still viewed as originating within the organism.

Piaget's Theory of Cognitive Development. Jean Piaget (1896–1980), a Swiss biologist and philosopher, studied how people come to know their world. **Piaget's theory of cognitive development** addresses the development of children's intellectual organization and how they think, reason, perceive, and make meaning of the physical world. His theory includes four periods, each of which subsumes a number of stages (Table 21-2). He recognized that people move through these specific periods at different rates but in the same sequence or order (Berk, 2006; Crain, 2005). Piaget also theorized that this would be true in all cultures. He acknowledged that biological maturation plays a role in this developmental theory but believed that rates of development depend on the intellectual stimulation and challenge in the environment of the person. Piaget found that children acquire knowledge through acting on the environment. In other words, the individual plays an active role in his or her development.

Mechanisms of Cognitive Development. Although it is helpful to be aware of the stages, the importance of Piaget's theory is that development is considered a spontaneous process in which individuals play an active role in their own development. Environmental challenges are internalized through the mechanisms of assimilation and accommodation. **Assimilation** is the process of making sense of new information in comparison with what is already known. **Accommodation** is the process of adapting ways of thinking to a new experience or new information. Together, these processes reflect adaptation to new information or experience. In a health care situation, a person who has a headache can evaluate it as an everyday or usual experience. In this process, the person is assimilating it to what he or she knows already as the experience of his or her body; that is, the person occasionally has headaches. When headaches become extreme or constant, then the person needs to understand the headache pain differently in the experience of his or her body. For instance, the person may learn to see himself or herself as a person who has migraines or as a person with a brain tumour who requires surgery.

The mechanisms of cognitive development apply across the lifespan and to all patient situations. Thus, they also apply to the moral theories and theories of adult development that are described in the following sections.

Nursing Implications of Cognitive Development. Most patients need to know about new ways of adjusting or behaving with regard to their health. Assimilation and accommodation represent adaptation of the patient to new health challenges. You need to support this process by providing information and support as patients come to terms with new health situations. You must also offer positive feedback when patients successfully adapt to their challenges.

Moral Developmental Theories

Moral developmental theories are a subset of cognitive theory and describe the development of moral reasoning. *Moral reasoning* is how people think about the rules of ethical or moral conduct, but it does not predict what a person would actually

► TABLE 21-2 Piaget's Theory of Cognitive Development

Stage	Description	Nursing Implications
Period 1: Sensorimotor (birth to 2 years of age)	The infant develops the schema or action pattern for dealing with the environment (Berk, 2006; Singer & Revenson, 1996). These schemas may include mouthing, looking, vocalizing, grasping, or hitting (Figure 21-2). Schemas become self-initiated activities; for example, the infant who learns that mouthing or sucking achieves a pleasing result generalizes the action to suck fingers, blanket, or clothing. Successful achievement leads to greater exploration. In the second year, children are able to form primitive mental images as they acquire object permanence. Before this, they do not realize that objects out of sight exist. When a 6-month-old is shown a toy before it is hidden, he or she will not search for it. At 18 months, the child can understand that even if it cannot be seen, it still exists and will search for it.	Educate parents about the need to promote infants' exploration of the environment. Such education supports development of action patterns that help the children achieve motor and cognitive skills. Observe parents during interactions with their infants. Reinforce parents' sensitivity and responsiveness to infant behaviours.
Period 2: Preoperational (2 to 7 years of age)	Children learn to think with the use of symbols and mental images. Still egocentric, the child sees objects and people from only one point of view: the child's own. Play is the initial method of nonlanguage use of symbols. This is a time of parallel play. Parallel play can be observed as children engage in activities side by side without a common goal. Imitation and make-believe play are ways to represent experience (Berk, 2006; Singer & Revenson, 1996). Later, language develops and broadens possibilities for thinking about the past or the future. Children can now communicate about events with others. As the language fits into a logical form, it mirrors the thinking process at the time.	Recognize the use of play as the way the child understands the events taking place. Parents can be assisted in the use of play materials such as toy thermometers and stethoscopes to encourage children to communicate feelings about health care procedures. Parents can also be encouraged to read and use rich language with their children to promote literacy and language development.
Period 3: Concrete operations (7 to 11 years of age)	Children achieve the ability to perform mental operations. For example, the child can think about an action that before was performed physically. At the earlier stage, the child could count to 10, but at this stage, he or she can count and understand what each number represents. Children can describe a process without actually performing it. At this stage, they are able to coordinate two perspectives. In other words, they can appreciate the difference between their perspective and that of a friend. Reversibility is the primary characteristic of concrete operational thought. Children can mentally reverse the direction of their thoughts. Children can mentally classify objects according to their quantitative dimensions, known as seriation. Another major accomplishment of this stage is conservation, or the ability to see objects or quantities as remaining the same despite a change in their physical appearance (Berk, 2006; Singer & Revenson, 1996). Children can begin to cooperate and share with new information about the acts they perform.	Encourage parents to guide the child to perform helpful activities within the home, such as doing chores in exchange for privileges (television or computer time, play with friends). Parents can encourage children to take another person's perspective or to plan ahead in school work deadlines.
Period 4: Formal operations (11 years to adulthood)	The individual's thinking moves to abstract and theoretical subjects. Thinking can venture into such subjects as achieving world peace, finding justice, and seeking meaning in life. Adolescents can organize their thoughts in their minds. They have the capacity to reason with regard to possibilities. New cognitive powers allow the adolescent to achieve more far-reaching problem solving. This thinking matures, and the depth of understanding increases with experience.	Include the adolescent in decision making about his or her own health care that is based on his or her ability to think abstractly.

do in a given situation. *Moral development* is the ability of an individual to distinguish right from wrong and to develop ethical values on which to base his or her actions (Berk, 2006). Although various theorists have addressed moral development, Piaget and Kohlberg proposed the most comprehensive theories of moral development. These theories are within the organicism tradition because they are grounded in cognitive development theory and development is seen as originating from within the individual. The mechanisms of cognitive development and the general nursing interventions also apply to the moral development theories because they emerged from the original work of Piaget.

Piaget's Theory of Moral Development. Piaget believed that moral development goes through a series of successive stages, just as cognition and learning do. **Piaget's theory of moral development** presents three stages of morality: the **premoral stage**, the **conventional stage**, and the **autonomous stage**. In the premoral stage, the child feels no obligation to follow rules. In the conventional stage, children follow the rules set up by people in authority, such as their parents, teachers, clergy, or police. When a person reaches the stage of autonomous morality, moral judgements are based on mutual respect for the rules. A person also considers the consequences of a moral decision. In making moral judgements that involve

Figure 21-2 Successfully achieving action patterns, such as grasping, leads to learning and more exploration.

others, the person at this stage starts to consider information related to the subjective intent (Berk, 2006).

Piaget believed that children initially follow the rules without understanding them. Children see these rules as fixed and handed down by adults or by God and therefore think they cannot change them. Young children base their moral decisions on the extent of the consequences to the action, not necessarily on the action itself. For example, a young child will not eat a cookie before supper, not because the mother said not to but because the child is afraid of the punishment that would result if he or she did. Around 10 or 11 years of age, children's cognitive ability matures and the rules they follow are understood within the context of community life. Children understand that the rules can be modified "by legal channels" if everyone agrees to change the rules (Singer & Revenson, 1996). Moral maturity is the internalization of the principles: that is, the desire to weigh all of the relationships and circumstances before making a decision.

Kohlberg's Theory of Moral Development. Lawrence Kohlberg (1927–1987) expanded on Piaget's moral developmental theory. From a series of moral dilemmas presented to boys aged 10, 13, and 16 years, he identified six stages of moral development occurring at three levels (Kohlberg, 1981; Table 21-3). Kohlberg found a link between moral development and Piaget's cognitive development theory. He theorized that a child's moral development does not advance if the child's cognitive development does not also mature. In this way, **Kohlberg's theory of moral development** follows Piaget's cognitive developmental theory. According to Kohlberg, levels and stages do not occur at specific ages, and people attain different levels of moral development.

Kohlberg's Critics. Although Kohlberg is recognized as a leader in moral developmental theory, critics have questioned the applicability of his study beyond the study population of male adolescents of the Western philosophical tradition.

Research attempting to support Kohlberg's (1981) theory with people raised in the Eastern philosophies found that those study participants never proceeded beyond stages 3 or 4 of Kohlberg's model. Does that mean that they have not reached as high a level of moral development as most of the adults raised in the Western traditions? Or is it that Kohlberg's research design did not allow a way to measure moral development in people raised within a different culture?

Kohlberg's (1981) study has also been criticized for age and gender biases. Gilligan (1982), an associate, concentrated on the differences in Kohlberg's findings that could have been related to gender. According to Gilligan, all developmental theories are subject to gender bias, and only since the 1990s have scholars researched and recognized the differences between men and women in the way they think and how they have been raised to make decisions (Kail, 2002).

Gilligan's Theory. Carol Gilligan (1936–present) proposed that Kohlberg's (1981) theory is biased in favour of men. She believed that men and women develop in parallel ways, with one not being superior to the other. Gilligan's argument is basically that the developmental difference between women and men is in relationships and issues of dependency (Berk, 2006; Crain, 2005; Gilligan, 1982). Separation and individuation are critically tied to male development. **Separation** refers to the boy's recognition of biological distinctness and is based on his emergence from a dependent relationship with his mother. This separation from the mother is essential for the boy in his development of masculinity. Girls do not need to separate from their mothers to achieve feminine identity; it is through this attachment to their mother that their identity is formed. In most developmental theories, the achievement of increasing separation is a developmental norm. When women are measured against this norm as it relates to their need to maintain relationships, they are seen as failures or as less evolved developmentally. **Individuation** is based on the child's awareness of differences in will, viewpoint, and needs. This process enables the individual to gradually assume a more independent role and identity.

Male moral development may focus on logic, justice, and social organization, whereas female moral development focuses on interpersonal relationships. Of interest is that in studies whose research design is based on Gilligan's critique, findings have been inconclusive. As a result, Gilligan's position remains controversial (Cavanaugh & Blanchard-Fields, 2006).

Psychoanalytic and Psychosocial Tradition

Theories in the **psychoanalytic and psychosocial tradition** describe the development of personality, thinking, behaviour, and emotions. This development is thought to occur with varying degrees of influence from internal biological forces and external societal and cultural forces.

Sigmund Freud

The first scholar to provide a formal, structured theory of personality development was Sigmund Freud (1856–1939). His goal was to promote successful participation in society through the development of balance between pleasure-seeking drives and societal pressures. In **Freud's psychoanalytic model of personality development**, he asserted that mature adults should have a strong sense of conscience that allows for the experience of pleasure within the boundaries of society. He

► TABLE 21-3 Kohlberg's Moral Development Theory

Level and Stage	Description	Nursing Implications
Level I: Preconventional level	The person reflects on moral reasoning based on personal gain. The person's moral reason for acting, the "why," relates to the consequences that the person believes will occur. These consequences can occur in the form of punishment or reward. Therefore, children may view illness as a punishment for fighting with their siblings or disobeying their parents.	As a nurse, you should be aware of this thinking and reinforce teaching that the child cannot become ill because of wrongdoing.
Stage 1: Punishment and obedience orientation	Response to a moral dilemma is in terms of absolute obedience to authority and rules. Avoidance of punishment or the unquestioning deference to authority is characteristic behaviour. The child will do something because an authority figure tells him or her to do it.	
Stage 2: Instrumental relativist orientation	The person recognizes that more than one view may be correct. The decision to do something morally correct is based on satisfying one's own needs and occasionally the needs of others.	
Level II: Conventional level	The person sees moral reasoning based on his or her own personal internalization of societal and others' expectations. A person wants to fulfill the expectations of the family, group, or nation; develop loyalty to the dominant order; and actively maintain, support, and justify the order. Moral decision making at this level moves from "What's in it for me?" to "How will it affect my relationships with others?"	You may observe this level of moral development when family members make end-of-life decisions for their loved ones. Grief support will involve an understanding of the level of moral decision making of each family member (see Chapter 28).
Stage 3: Good boy–nice girl orientation	The individual wants to please others and win approval by "being nice," which means having good motives, showing concern for others, and keeping mutual relationships through trust, loyalty, respect, and gratitude.	
Stage 4: Society-maintaining orientation	Focus expands from relationships with others to societal concerns. Correct behaviour is doing one's duty, showing respect for authority, and maintaining the social order. Adolescents in this stage may choose not to attend a party at which drugs will be used, not because they are afraid of getting caught but because they know that using drugs is not healthy.	
Level III: Postconventional level	The person finds a balance between basic human rights and obligations and societal rules and regulations. Individuals reject moral decisions based on authority or conformity to groups in favour of defining their own moral values and principles. Individuals at this stage start to envision an ideal society.	You focus not only on your individual practice but also on social determinants that affect the well-being of a community, such as poverty and homelessness.
Stage 5: Social contract orientation	An individual follows the laws but recognizes the possibility of changing the law to improve society. The individual also recognizes that different social groups may have different values but believe in basic rights, such as liberty and life.	
Stage 6: Universal ethical principle orientation	"Right" is defined by the decision of conscience in accord with self-chosen ethical principles. These principles, such as the Golden Rule, are abstract and appeal to logical comprehensiveness, universality, and consistency (Kohlberg, 1981). Whereas stage 5 emphasizes the basic rights and the democratic process, stage 6 defines the principles by which agreements will be most just.	

believed that two internal biological forces essentially drive psychological change in the child: sexual (**libido**) and aggressive energies. Motivation for behaviour is to achieve pleasure and avoid pain created by these forces. These forces come into conflict with the reality of the world as maturational changes occur.

Freud's theory accounts for five psychosexual developmental stages, each associated with different pleasurable zones that serve as the foci for gratification and bodily pleasure (Berk, 2006; Kliegman et al., 2007; Table 21-4). Freud's theory has been soundly criticized for gender and cultural biases and for an extreme focus on sexuality in development. Freud's critics contend that people are more influenced by their life experiences than by their sexual energies. Despite these criticisms, Freud provided a basis for observation of emotion,

behaviour, and sexuality that has been very influential in the development of many other psychoanalytic theories. Indeed, many agree that development is an ongoing process of resolving conflict between issues of biological maturation and societal expectations.

Mechanisms of Freud's Theory. Components of personality emerge through Freud's developmental stages. The mechanisms of Freud's personality development theory are the **id**, the **ego**, and the **superego**. Freud believed that the functions of these mechanisms regulate behaviour. The **id**—basic instinctual impulses and drives to achieve pleasure—is the most primitive part of the personality and originates in the infant. The **ego** represents the reality mechanism mediating conflicts between the environment and the forces of the **id**. The **ego** helps us judge reality accurately, regulate impulses, and

▶ TABLE 21-4 Freud's Five Stages of Psychosexual Development

Stage	Description	Nursing Implications
Stage 1: Oral (birth to age 12–18 months)	Initially, sucking and oral satisfaction is not only necessary for living but also extremely pleasurable in its own right. Late in this stage, the infant begins to realize that the mother or parent is something separate from self. Disruption in the physical or emotional availability of the parent (e.g., inadequate bonding or chronic illness) could have an impact on the infant's development.	For an infant, feeding and sucking produces pleasure and comfort and promotes self-regulation. Teach parents that feedings should be offered whenever the infant requires them. As well, encourage parents to help their infants self-soothe by making the infant's hands available for sucking.
Stage 2: Anal (ages 12–18 months to 3 years)	The focus of pleasure changes to the anal zone. Children become increasingly aware of the pleasurable sensations of this body region with interest in the products of their effort. Through the toilet-training process, the child is asked to delay gratification in order to meet parental and societal expectations.	Teach the parents that toilet training should be as positive an experience as possible. Praise helps the child achieve a sense of control. Development is not always a smooth, uninterrupted process of moving forward to more advanced stages. Teach parents to understand that successes are often accompanied by failures in the normal progression of development. Assure parents that a child's identifying with the parent of the same sex is a normal developmental phase.
Stage 3: Phallic or Oedipal (ages 3–6 years)	The genital organs become the focus of pleasure. The boy becomes interested in the penis; the girl becomes aware of the absence of the penis, known as <i>penis envy</i> . This is the time of exploration and imagination as the child fantasizes about the parent of the opposite sex as his or her first love interest, known as the <i>Oedipal complex</i> (in boys) or <i>Electra complex</i> (in girls). By the end of this stage, the child attempts to reduce this conflict by identifying with the parent of the same sex in a way to win recognition and acceptance.	Encourage the child to pursue physical and intellectual challenges that will provide opportunities to explore and develop abilities and competencies.
Stage 4: Latency (ages 6–12 years)	Sexual urges from the earlier Oedipal stage are repressed and channelled into productive activities that are socially acceptable. Within the educational and social worlds of the child, much is to be learned and accomplished. The child places energy and effort into these worlds.	Educate parents that the child needs to be encouraged to be independent and make his or her own decisions, within safe limits. Help parents to empathize and identify with their growing adolescent. As parent-child conflicts associated with increasing adolescent independence arise, empathy will help the parent to understand the adolescent's point of view.
Stage 5: Genital (puberty through adulthood)	This is a time of turbulence when earlier sexual urges reawaken and are directed toward an individual outside the family circle. Unresolved prior conflicts surface during adolescence. Once conflicts are resolved, the individual is then capable of having a mature adult sexual relationship.	

make good decisions. The third mechanism, the **superego**, performs regulating, restraining, and prohibiting actions. Often referred to as the *conscience*, the superego is influenced by the standards of outside social forces (parent, teacher).

Nursing Implications of Freud's Theory. The functions of the id, ego, and superego form the historical basis of many, if not all, subsequent theories of personality and social emotional development. You need to remember that according to Freudian theory, mature human personality is the product of conflict between instinctual drives to achieve pleasure and the restraints of adaptive human society. When activities associated with basic pleasure (e.g., eating, sexual activity, and elimination) are altered by illness or disability, knowledgeable and empathetic nursing care is required.

Erikson's Theory of Eight Stages of Life

Erik Erikson (1902–1994) expanded Freud's psychoanalytic stages into a psychosocial model that covered the whole lifespan, not just childhood and adolescence (Erikson, 1993, 1997; Kliegman et al., 2007). He broadened the factors responsible for influencing development to include socialization.

According to **Erikson's theory of eight stages of life**, each person goes through eight stages of development (Table 21-5). In each stage, the person needs to accomplish a particular task before moving on to the next stage. Each task is framed with opposing conflicts that the person must balance. For example, an adolescent needs to develop a sense of personal identity despite many conflicting societal choices (stage 5, identity versus role confusion). Each stage builds upon the successful resolution of the previous developmental conflict. Readiness for the task is necessary for success. Once mastered, tasks are challenged and tested during new situations or at times of conflict (Hockenberry & Wilson, 2007). For example, the infant's trust is built through consistent, reliable caregiving, and the concept of trust is tested when an infant is hospitalized or after the birth of a new sibling.

Mechanisms of Erikson's Theory. *Maturation* and *ego* activity are the primary mechanisms of development in Erikson's theory of eight stages of life. The ego mediates the conflicts between the biological needs and societal norms, and maturation establishes the timeline of this mediation. The developmental result of these mechanisms is described as an

► **TABLE 21-5** Erikson's Theory of Eight Stages of Life

Stage	Description	Nursing Implications
1. Trust versus mistrust (infancy: birth to age 1 year)	The infant learns to trust others. Trust is achieved when the infant will let the caregiver out of sight without undue distress. Key to this stage is consistent caregiving. The question answered at this stage is "Can I trust the world?"	The parent's struggle with building competence can be assisted by your use of anticipatory guidance and other educative interventions. The parent may need guidance to understand the importance of a safe, nurturing environment when meeting the child's needs.
2. Autonomy versus sense of shame and doubt (toddler years: ages 1–3 years)	The toddler learns to be independent and develops self-confidence. Not learning independence creates feelings of shame and self-doubt. Independence is accomplished through self-care activities, including walking, feeding, and toileting. Toddlers also develop autonomy by making choices. The question answered at this stage is "Can I control my own behaviour?"	Nurses can use empathetic guidance to offer support for and understanding of the challenges of this stage. Parents can be taught to use nonviolent disciplinary methods with their children that promote safety, yet discipline. Teach parents to offer children a limited number of choices, so as not to overwhelm, but to promote children's developing sense of self-efficacy and competence.
3. Initiative versus guilt (preschool years: ages 3–6 years)	The child learns to initiate his or her activities. Accomplishing this task teaches the child to seek challenges in later life. Children use fantasy and imagination to explore their environment. Conflicts often arise between the child's desire to explore and the limits placed on his or her behaviour. These conflicts may lead to feelings of frustration and guilt. The question answered during this stage is "Can I become independent of my parents and explore my limits?"	Teaching impulse control and cooperative behaviours to the child are necessary at this stage. Children can be shown appreciation for independent behaviours that demonstrate prosocial skills such as sharing, kindness to others, and helping with household chores.
4. Industry versus inferiority (middle childhood: ages 6–11 years)	The child develops a sense of competence in physical, cognitive, and social areas. Not learning new skills may lead to a sense of inadequacy and inferiority. Successfully achieving this task leads to positive attitudes toward work in adulthood (Erikson, 1993). The question answered at this stage is "Can I master the skills necessary to survive and adapt?"	You can encourage parents to offer the child many opportunities to pursue new interests and challenges in extracurricular activities such as sports, music, and art.
5. Identity versus role confusion (adolescence: ages 12–18 years)	The task of adolescence is to try out several roles and form a unique identity. Dramatic physiological changes associated with sexual maturation also mark this stage. Acquiring a sense of identity is essential for making later adult decisions such as vocation or marriage partner. New social demands, opportunities, and conflicts arise in relation to the emergent identity and separation from family. The question answered at this stage is "Who am I, and what are my beliefs, feelings, and attitudes?"	You can provide education and anticipatory guidance for the parent about the changes in and challenges to the adolescent. You can also assist hospitalized adolescents in dealing with their illness by giving them enough information to allow them to make decisions about their treatment plan.
6. Intimacy versus isolation (young adulthood: ages 18–35 years)	The primary task of young adulthood is to form close, personal relationships. This is the time to become fully active in the community. If young adults have not achieved a sense of personal identity, they may be unable to form meaningful attachments, and they experience feelings of isolation. The question answered during this stage is "Can I give of myself fully to another?"	Understand that during hospitalization, young adults may benefit from the support of their partners or significant others because this support helps fulfill their need for intimacy.
7. Generativity versus self-absorption and stagnation (middle adulthood: ages 35–65 years)	The task of middle adulthood is to help younger people. The ability to expand one's personal and social involvement is crucial for this stage of development. Middle-aged adults should be able to see beyond their needs and accomplishments and view the needs of society. Dissatisfaction with one's achievements often leads to self-absorption and stagnation. The question answered during this stage is "What can I offer succeeding generations?"	You can assist adults in choosing creative ways to foster social development. Middle-aged people may find a sense of fulfillment from volunteering some time in a local school, hospital, or place of worship.
8. Integrity versus despair (old age: age 65 years and older)	Older adults reflect on their life and feel satisfaction or disappointment. By suffering physical and social losses, such as those through retirement or illness, the adult may also suffer loss of status and function. The person may also have internal struggles, such as the search for meaning in life. Meeting these challenges creates the potential for growth and wisdom (Figure 21-3). The question answered during this stage is "Has my life been worthwhile?"	You can contribute to the valuing of people at all ages and stages in their communities. For example, by promoting older adults' involvement in volunteer activities, such as youth mentoring, that you display value for the skills and experience of older people, and such mentoring helps the younger generation feel important.

Figure 21-3 Maintaining independence is important to a person's self-esteem.

epigenesis (successive gradual change). If the process is adaptive, then a person has successive positive outcomes.

Nursing Implications of Erikson's Theory. The theory of the eight stages of life implies that the quality of early developmental work is important. For instance, children who live in environments in which violence is common and trust has not been attained are at greater risk of experiencing poor intimate relationships. The mechanism of epigenesis implies that the original required trust elements cannot be retrieved; at best, such a person can learn only to live with the fear and anger associated with this mistrust. You therefore need to practice within the health promotion model to build the familial, community, and societal supports necessary for growing, vulnerable children to achieve successful transitions at each stage (e.g., trust, autonomy, initiative).

John Bowlby

John Bowlby (1907–1990) was a child psychiatrist interested in children's mental health. According to **Bowlby's attachment and separation theory**, the conflict between attachment and separation needs to be resolved to produce healthy social and emotional developmental outcomes across the lifespan. **Attachment** means a bond or tie between an individual and another person, such as a parent or caregiver. A basic premise of the theory is that the quality of attachment relationships stems from interactions between infants and caregivers. These interactions reflect the degree to which infants can rely on their caregivers to provide proximity and companionship, a safe haven in the presence of threat or anxiety, and a secure base from which to explore. Failure to achieve secure attachment results in an inability throughout the lifespan to separate from

BOX 21-2 NURSING STORY

Jonathan is five years old. His mother has brought him to the pediatrician at the advice of his kindergarten teacher. You are the clinic nurse, charged with taking Jonathan's history. His mother removes Jonathan's winter coat and collects his mittens. She takes time to locate crayons and paper for Jonathan during the office visit. However, Jonathan does not settle for long. As you begin your assessment, you observe Jonny, as she calls him, spend a minute with the crayons before breaking one and then moving on to examine the stethoscope and then the next item in the office that intrigues him more. Jonny rips the paper and his mother makes no move to correct him. He smiles at you and seems content to move chaotically about in the office.

As you proceed through your assessment, you learn that Jonny accomplished typical milestones (walking, talking, toilet training) on time and had a few ear infections but no other physical health problems. His weight and height are normal. He gets along well with the other kids, except for the occasional skirmish over a toy. His mother notes that he does not sit still for very long, but, she says, Jonny loves to be read to and can curl up for half an hour easily during story time with her. The mother tells you that since her military husband was deployed three months ago, she rarely has individual time for Jonny or her other children. His dad could "make him mind" and so since his dad's deployment, she has given up on trying to make him sit still in church, leaving him instead in a supervised playroom. She adds that her kids miss their dad but Jonny's older siblings grew accustomed to his absences over time. As she begins to talk about Jonny's dad, Jonny climbs into his mother's lap and starts playing a shooting game with a car on the counter. Jonny's mom gently "shoo's" him away. Jonny slides to the floor but returns with a book held out to his mother. She says, "Sorry, not now, Jonny," and tells you the teacher's concern about his activity level, inability to hold a pencil properly, and failure to pay attention to learning tasks in class. The mother relays the teacher's concern that he may have attention deficit-hyperactivity disorder. You wonder whether Jonny's activity level has anything to do with his father's deployment (separation from his dad) and the decreased time that Jonny's mother has for him (separation anxiety and lack of secure base). The mother wonders whether medication would help Jonny have an easier time in kindergarten, and she asks you for your opinion.

caregivers and reconnect to new relationships (including work, friendship, and intimate relationships) in a healthy way.

Mechanisms of Bowlby's Theory. Early in life, two complementary behavioural systems, attachment and caregiving, combine into a self-regulating system that supports people in their healthy attachments to and separations from others. The child's experiences within this self-regulating system cause the child to develop a cognitive working model (or "map") of self, other, and the relationship between them. The ability to regulate emotion and behaviour (Box 21-2) are influenced by this working model at each developmental stage throughout life.

Patricia Crittenden

Psychologist Patricia Crittenden (1945–present) was heavily influenced by the work of attachment theorists Bowlby and Ainsworth (1979) in developing her **dynamic maturational model of attachment** (Crittenden, 2008; Crittenden & Claussen, 2003). In this model, behavioural and psychiatric developmental disorders are considered within the context of family

attachment relationships. Unlike the previous work of attachment theorists, the model considers the impact of intimate relationships on development over the lifespan.

Mechanisms of the Dynamic Maturational Model.

The interaction between brain development and experiences with caregivers is central in the development of self-protective strategies that individuals use over their lifespan (Box 21-3).

BOX 21-3 RESEARCH HIGHLIGHT

Toxic Stress and Development

In response to stressors such as difficult and challenging experiences, humans physiologically respond by increasing the capacity to think and act. Energy stores are mobilized and heart rate and blood pressure are increased to enable more attention, awareness, and responsiveness to the environment. When stress is controllable, short-lived, and predictable, it can help us learn to be adaptive and resilient. This is a good form of stress. Some forms of stress are tolerable even though they challenge our abilities to cope. The death of a loved one or moving to a new city are examples of inevitable forms of adverse events that are made tolerable by support from our social network and by the fact that many other people have faced similar experiences. But what if the challenges we face are uncontrollable, unpredictable, and pervasive? This is toxic stress.

Toxic stress is a form of stress that results in chronic activation of the biological stress response system with harmful consequences for child development. Experiences that are chronically disruptive, abusive, neglectful, or unpredictable flood the brain with chemicals that, in large persistent doses, impair neuronal growth and ultimately make it harder for the brain to form healthy connections. In this way, toxic stress leaves a lasting biological fingerprint of damage on brain structure and function.

For example, parents suffering from mental illness, addictions to substances of abuse, or domestic violence are less able to respond sensitively to their infants to meet their needs, placing the infants at risk for unpredictable, neglectful, or abusive parenting. As infants are completely reliant on their parents to have their basic needs met, these situations chronically activate infants' stress systems and produce changes to the structure and function of some brain regions.

Two major brain regions that are known to be affected by toxic stress are the hippocampus and the prefrontal cortex. These brain regions are particularly important to the development of memory and self-regulation—the foundations of school and social success. Over time, the effects of toxic stress on brain structure and function can lead to shifts in patterns of behaviour from more organized to more habitual with the result that children become more rigid and less capable of independent problem solving.

The effects of toxic stress are particularly worrisome in early childhood because the brain is exquisitely sensitive to experience during this phase of rapid brain development. As well, children's future brain development builds upon current and past brain development. Thus, changes in brain structure and function due to toxic stress produce cumulative changes—affecting not only current aspects of development for a given stage, but also the next stage that builds upon previous growth. To summarize, it seems that the common adage “what doesn't kill you will make you stronger” is true of good stress but when it comes to toxic stress “what doesn't kill you now may kill you later.”

Reference: Letourneau, N., & Giesbrecht, G. (2011). Toxic stress in early caregiving and child health. *DMM News*, 11, 1–2.

Attachment strategies are employed to promote safety and security in relationships (Crittenden & Claussen, 2003; Crittenden & Landini, 2011). Patterns of attachment are dominated by “cognitive” and “affective” strategies and may be categorized as types A and C, respectively. People with type A patterns tend to minimize awareness of negative feelings, compulsively perform what they expect will be reinforced, and avoid doing what will be punished (Crittenden & DiLalla, 1988). People with type C patterns rely on feelings as guides to behaviour because they lack confidence in what will happen next. When familial relationships fail to protect the child (or adult parent), type A and type C coping strategies become more extreme. For example, a child reared by an unresponsive caregiver may learn that “acting out” elicits a needed response from the caregiver. As the child grows and becomes an adult, he or she may seek attention by extreme emotional outbursts, acting coercively or aggressively in other adult relationship (type C) (Crittenden & Kulbotten, 2007). Another pattern, type B, is characterized by a tendency to use a balance of type A and type C strategies.

Nursing Implications of the Dynamic Maturational Model. You need to design approaches that address both the quality of the attachment system and the caregiving system. Crittenden (2008) asserted that recognizing patients' attachment strategies is crucial for providing helpful treatments and reducing the risk of inappropriate treatment. For instance, in the situation in which a young child is hospitalized, you would need to consider the security of the child and to provide high-quality substitute care, including making developmentally appropriate efforts to keep the child attached to his or her primary caregiver (e.g., using pictures, phone calls, liberal visiting hours, parent sleepovers). If you are working in mental health care, you need to recognize that patients' apparently maladaptive coping strategies (e.g., obsessive-compulsive disorder, anxiety) may be strategies developed to cope with adverse relationships with attachment figures. Alternatively, in working with parents in impoverished environments, you need to support the caregivers through the provision of material, social, and educational resources that will promote safety and security of both adults and children. You need to advocate for appropriate support resources for families in which caregiving may be compromised as a result of stress associated with parental poverty, mental illness, or lack of education (Middlebrooks & Audage, 2008; Mustard, 2006).

Havighurst's Developmental Tasks

Robert Havighurst (1900–1991) was influenced by Erikson's work and observations of the developmental tasks crucial for healthy development. Havighurst defined a series of age-specific essential tasks, such as learning to walk, getting ready to read, learning social and gender roles, developing independence, selecting a mate, rearing children, and, finally, adjusting to decreasing physical strength and health. The essential tasks arise from predictable internal and external pressures, such as increasing physical maturity, cultural pressure of society, and the individual's personal goals and aspirations.

According to Havighurst's developmental tasks, several sources of pressure may be present at the same time. Increasing physical maturity is associated with the development of skills such as walking, talking, or eating. Cultural pressure creates the conditions necessary to learn social behaviours and ethical norms. An adolescent girl may be physically able to bear a child, but the preparation and timing for the onset of

► TABLE 21-6 Developmental Theorists for Adult Stages

Adult Stages	Erikson's Description	Havighurst's Description
Early-early adult (ages 16–22 years)	Intimacy versus isolation	Early adulthood stage
Middle-early adult (ages 22–28 years)	Ability to form intimate relationships	Selecting a mate Learning to live with a marriage partner Starting a family Rearing children Getting started in an occupation Taking on civic responsibilities Finding a congenial social group
Early-middle adult (ages 28–45 years)	Generativity versus self-absorption and stagnation Ability to expand personal and social involvement	Middle age Assisting teenage children to become responsible adults Achieving adult social and civic responsibility Reaching and maintaining satisfactory performance in one's occupation Developing adult leisure-time activities Relating to one's spouse as a person Accepting and adjusting to the physiological changes of middle age Adjusting to aging of parents
Late adult–old age (age 45 years and older)	Integrity versus despair, disgust Ability to adapt to changes in lifestyle, functional level, and family structure	Later maturity Adjusting to decreasing physical strength and health Adjusting to retirement and reduced income Adjusting to death of a spouse Establishing an affiliation with one's age group Adopting and adapting social roles in a flexible way Satisfactory physical living space

parenthood can also be considered from a perspective of pressure from both the youth and adult cultures.

Havighurst believed that at certain critical periods, the individual is most receptive to the learning necessary to achieve success in performing these tasks. Effective learning and achievement of tasks during one period lead to happiness and success with later tasks. Failure leads to unhappiness, disapproval by society, and difficulty with later tasks. An example is the struggle that adolescents might experience in preparing for a work career after having failed to develop fundamental skills in reading and math.

Havighurst's theory is limited in its cultural application, according to critics who believe that it describes developmental milestones from the perspective of middle-class norms within the United States. It would be difficult to fit all cultural or ethnic mores within this theoretical framework.

Mechanisms and Nursing Implications of Havighurst's Theory. Havighurst's work built on that of Freud and Erikson. Therefore, the mechanisms and nursing implications from Freud and Erikson also apply to Havighurst's developmental tasks (Table 21-6).

Mechanistic Tradition

According to the **mechanistic tradition**, the organism is similar to a machine. Development depends on the level of stimulation, the kind of stimulation, and the history of stimulation from the environment. The environment is considered to activate human development (Bornstein & Lamb, 1999), and behaviour is seen as responsive to environmental forces rather than driven only by internal causes such as maturation. Social learning theory follows from this tradition and is presented in Chapter 20.

Contextualism

The way that human development is described and explained is increasingly tied to the understanding of environment and context. Developmental theories within the **contextual tradition** focus on the relationship between the individual and his or her social context. Within this tradition, the individual and the environment are viewed as mutually influential, acting on one another in dynamic interaction (Bornstein & Lamb, 1999). Human development is the process of continuously adapting to changing environments.

Bioecological Theory

Urie Bronfenbrenner (1917–2005), a developmental psychologist at Cornell University, developed a theory that stresses the importance of the interaction between the developing individual and his or her surrounding social environments. **Bronfenbrenner's bioecological theory** involves considering multiple “layers” of the environment:

- The **microsystem** consists of the immediate settings, activities, and personal relationships of the individual. Examples are family, classroom, workplace, and recreation group.
- The **mesosystem** is made up of the relationships between the different settings in which the person spends time. Examples are relationships between families and schools, between workplaces and schools, and between families and spiritual organizations (church parish, mosque, temple), and spiritual organizations and schools.
- The **exosystem** is a set of specific social structures that do not directly contain the individual but exert direct and indirect influence on individual development. Examples are the health care system, the education system, the justice system, and religious institutions.

- The **macrosystem** consists of all of the elements contained in the individual's microsystem, mesosystem, and exosystem, as well as the general underlying philosophy, cultural orientation, and values by which the person lives (Salkind, 2004). Examples are overarching dimensions such as political orientation, economic model, and cultural values.

Mechanisms of the Bioecological Theory. Lev Semenovich Vygotsky (1896–1934) introduced a concept called the **zone of proximal development**, which is the key developmental mechanism of ecological theories. This zone is the space between the individual's potential and his or her actual developmental status. For instance, a toddler may have a 10-word vocabulary but potentially could have a repertoire of hundreds of words. Activity that links those two states promotes development. For instance, parents who use joint referencing (looking at things that their toddlers are looking at and naming them) promote toddler vocabulary development within the zone of proximal development.

Bronfenbrenner's modern conception of developmental processes expands upon Vygotsky's idea of the zone of proximal development. In language acquisition, developmental support processes occur in all levels of the system. At the macrosystem level, a process supporting language development in young children would be the adoption of a national child care policy to support working parents. Such a policy would inform regulations concerning issues such as education level of child care workers, ratio of children to workers in child care centres, and space requirements per child.

Nursing Implications of the Bioecological Theory.

An appropriate goal of nursing practice is to influence wellness by promoting health in all layers of the bioecological system. The ecological model applies to nursing practice beyond the individual level of health promotion to higher levels of the social context. Therefore, Bronfenbrenner's theory fits well with the current emphasis on primary health care (Box 21-4).

Dialecticism

In the **dialectic tradition**, all developmental theories are considered mutually interactive. Developmental theorists are increasingly proposing that change or development can occur within the framework of multiple theories. A key element of the dialectic tradition is the ability to incorporate multiple contexts. An example of a dialectic approach from the biomedical sciences is the theory of gene expression. The theory of gene expression links genetics, the environment, and their influences on human behaviour and disease. In the human development disciplines, examples of dialectical thinking include the growing awareness of the effect of the economic environment on human development at the population level. Resilience theory is an approach in which the interaction between two processes, previously studied separately, is examined.

Keating and Hertzman's Population Health Theory

Human development has historically been considered an individual characteristic. According to Daniel P. Keating (1949–present) and Clyde Hertzman's (1953–present) **population health approach**, human development is a population phenomenon. These Canadian developmental theorists referred to the strong association between the health of a population, developmental outcomes, and the social and economic forces affecting the larger society. They based their developmental

*** BOX 21-4**

FOCUS ON PRIMARY HEALTH CARE

Bronfenbrenner's Ecological Theory and Primary Health Care

Three principles of primary health care are to (1) foster public participation, (2) educate the patient in order to promote health and prevent illness, and (3) foster intersectoral collaboration. Bronfenbrenner's ecological model of human development fits well with these principles. At each environmental layer, nurses can initiate actions to promote health:

- **Microsystem**, which includes the individual and his or her immediate setting (e.g., family, school, workplace, neighbourhood). You can help the individual develop personal skills, healthy lifestyles and activities, and supportive environments. For example, you can help teach family members caring for an elderly parent how to balance family care and self-care to keep themselves healthy.
- **Mesosystem**, which consists of relations among the individual's various immediate settings. To strengthen the mesosystem, you can work toward strengthening community action. You can link the family to community supports such as adult respite services and older adults' activities groups.
- **Exosystem**, which comprises relations among structures, sectors, services, and policies. The exosystem is strengthened when nurses promote healthy public policy. You are practising at this level when you help develop links between typically separate services such as the health care system and the social service system. For example, you can volunteer to be on planning committees and other decision-making bodies.
- **Macrosystem**, which consists of societal values. To promote optimum health at the macrosystem level, the nurse can be an advocate for social change. For example, if you believe that more value should be placed on older adults in society, you may advocate for higher standards and staff-to-resident ratios in long-term care facilities. Such advocacy might include writing letters to the editor, joining community or national advocacy groups, and lobbying politicians.

theory on epidemiological evidence that improved literacy (one marker of human development) is related to improvements in family economic status, in school community economic status, and in national economic status (Hertzman, 2011).

Keating and Hertzman (1999) proposed that health, behaviour, and cognitive functions are largely set in early life and are then influenced further by succeeding events in the socioeconomic environment. **Developmental health** is defined as the physical and mental health, well-being, coping, and competence of human populations. Developmental health is primarily a function of the overall quality of the social environment, including the national socioeconomic environment, civil society, and social network. Keating and Hertzman's population approach to human development is outlined in Figure 21-4.

Mechanisms of the Population Health Theory.

Keating and Hertzman (1999) proposed three interrelated regulatory systems as the mechanisms for human population development: emotional regulation, attention regulation, and social regulation. Each regulatory system develops in interaction between the individual's biological processes and his or

Figure 21-4 Framework for human development and the social determinants of health. **Source:** Redrawn from Keating, D. P., & Hertzman, C. (Eds.). (1999). *Developmental health and the wealth of nations: Social, biological and educational dynamics* (p. 30). New York: Guilford Press.

her multiple socioeconomic environments. *Emotional regulation*, which involves the modulation of emotional reactions, plays an important role in competent social functioning. *Attention regulation*, which involves regulation of arousal and reactivity of the brain, contributes to the ability to pursue goals and respond to challenges to those goals. *Social regulation* involves regulation of social interactions, including aspects such as mutual affection and warmth, particularly in nurturing relationships. Together, these three regulatory systems are thought to influence later competence as individuals interact reciprocally with their socioeconomic environments.

Nursing Implications of the Population Health Theory. Nurses have typically focused on the health and well-being of patients. To promote well-being, health providers need to implement practices that take into account the impact of the socioeconomic context on the health of the individuals in society. The ecological levels of health promotion activities are directly applicable to the population health approach. A population health approach helps identify these socioeconomic factors and provides direction for designing nursing interventions that address them.

Resilience Theory

Resilience is defined as the maintenance of positive adjustment under challenging life conditions (Cicchetti & Curtis, 2007). This approach arose in the field of child psychiatry when clinicians observed that some children and adolescents were able to thrive in severely adverse conditions (e.g., poverty, maternal depression, and paternal criminality), whereas others faltered (Luthar, 2003).

Mechanisms of Resilience. Resilience theory focuses on the interaction between protective processes and vulnerability processes. **Vulnerability processes** (physical illness, psychological stresses, social risk) and **protective processes** (self-efficacy, good parenting and problem solving, social support acquisition and maintenance) are examined together to understand and explain human growth and development. Individual factors found to promote resilience include self-efficacy, positive attitude, literacy, social competence, and a history of success. Family-level processes that protect from adversity include coherent response to crisis, social supports, stability, flexibility, effective parenting, and responsibilities outside the home (Rutter, 2005). Community-level processes

that promote resilience include control over policy, collaborative and cooperative organization, widespread citizen participation in community, and volunteerism.

Resilience and family adaptation theory has been used to design interventions to support children and families at risk, focusing on protective processes within the context of key risk situations, usually defined by factors such as poverty, chronic illness, and civil conflict. This emphasis is a progression from the previous emphasis on only pathological processes, but the challenge is to design research that enables scholars to study both protective processes and vulnerability processes as they occur together.

Nursing Implications of Resilience. The focus of nursing practice is directly on the individual, family, and community factors that promote health. Nursing practice is usually used in situations that are stressful and challenging for individuals and families, such as illness and loss. Resilience theorists acknowledge the complexity of these moments and ask what nurses can use from these challenging situations that help the family succeed (Box 21-5). For example, a young single woman dealing with the birth of her first child will benefit from nursing interventions that focus both on protective processes (linking to support group, learning parenting skills) and on vulnerability processes (ensuring adequate health care, arranging for financial support).

Developmental Theories and Nursing

The diverse set of theories included in this chapter suggest that human behaviour is truly complex. No single theory successfully describes human growth and development in all its complexity. Theorists demonstrate their own values and beliefs in their focus and the subjects chosen for their work, and they work within cultural and historical perspectives. The theories described in this chapter are meant to provide the basis for meaningful thought and observation of an individual's pattern of growth and development and the role of environments in it. This observation and reflection provide you with a framework within which you can predict human responses to health and illness and recognize deviations from the norm.

Patterns of growth and development help determine future patterns of adjustment to life (Edelman & Mandle, 2006). A clear understanding of these patterns and of the contexts

BOX 21-5 RESEARCH HIGHLIGHT

Supporting Parents: Can Intervention Improve Parent-Child Relationships?

Research Focus

Healthy child development has been identified as one of the key determinants of health and resiliency in adulthood. In two studies reported by Letourneau et al. (2001), researchers examined interventions aimed at improving the parent-child relationship and enhancing resiliency among children considered to be at risk because of poverty or parents' young age, inexperience, or lack of education.

Research Abstract

These two pilot studies were randomized control trials designed to test the effects of two support interventions. In the first intervention, Keys to Caregiving, a family-centred approach, was used to provide parents with tools necessary for high-quality interactions with their infants. A post-test experimental design was used to study 16 adolescent mothers and their infants. The second intervention, Natural Teaching Strategies, focused on developing mutually satisfying methods for parents to communicate with their preschoolers. A pretest-post-test design was used to study 29 families of children enrolled in Head Start programs. In both groups, parent-child interactions were enhanced in the treatment groups. Results of both interventions revealed the potential effect of supportive intervention on parent-child interactions over time.

Evidence-Informed Practice

- Helping parents develop realistic expectations of their child's development and improving the quality of parent-child relationships are important support mechanisms for families at risk.
- Parent training and support has the potential to positively alter the style of interactions between parents and children.

Reference: Letourneau, N., Drummond, J., Fleming, D., Kysela, G., McDonald, L., & Stewart, M. (2001). Supporting parents: Can intervention improve parent-child relationships? *Journal of Family Nursing*, 7(2), 159-187.

within which they occur assists you in planning questions for health screening and health history and in health teaching for patients of all ages. You need to consider an individual's development within the context of his or her families, social relationships, communities, and the larger society.

Developmental theories help you use critical thinking skills when you consider how and why people respond as they do. Your assessment of a patient requires a thorough analysis and interpretation of data to form accurate conclusions about a patient's developmental needs. To accurately identify patients' needs, you need the ability to consider developmental theory in data analysis. Typical developmental behaviours are compared with those projected by the developmental theory.

❖ KEY CONCEPTS

- Nurses provide care for individuals and families throughout their lives. Developmental theories provide a basis for nurses to assess, interpret, and understand the responses seen in their patients.
- Development continues throughout life.
- Individuals have unique patterns of growth and development within broad limits.

- Development is not just a series of distinct linear tasks; it is also a process that varies across and within individuals (Hartup, 2002).
- Three major categories of factors influence human growth and development: (1) genetic or natural forces within the person, (2) the environment in which the person lives, and (3) the interaction that takes place between these two.
- Theories within the organic tradition explore how individuals develop when mostly biological components are believed to stimulate developmental progress.
- Theories in the psychoanalytic and psychosocial tradition describe development of the human personality with regard to conflict resolution between the internal biological forces and the external societal and cultural forces.
- According to the mechanistic approach, human development and behaviour are responses to environmental forces rather than driven by internal causes such as maturation.
- Within the contextual tradition, the individual and the environment are viewed as mutually influential, acting on one another in dynamic interaction.
- In the dialectical tradition, the complete complexity of development is acknowledged. Theorists who work in this tradition strive to combine divergent ways of viewing human development.

❖ CRITICAL THINKING EXERCISES

1. A 50-year-old woman is anxious because her children, 20 and 23 years of age, are no longer living at home. Her husband is still working full-time but planning to retire in two years. She is concerned that she is not needed, and she is bored with her life. Identify the developmental task of Erikson's theory that best fits this woman's situation. How will you assist this patient in changing her lifestyle while understanding her developmental tasks?
2. A public health nurse conducting a routine assessment of an 18-month-old is concerned about the child being underweight for his age. Upon further discussion, the father reveals that he is not working at present and the family is having financial troubles. Using your knowledge of Bronfenbrenner's bioecological theory, what approach and subsequent strategies would be helpful for these parents?
3. Two 11-year-old girls are spending the day together at the mall. They exit one store, and one of the girls shows her friend a small purse that she stole from the store. Her friend is upset and wonders how she should respond. Use moral development theory to discuss this issue.
4. A woman visits her nurse practitioner at her local health clinic. The woman is struggling with depression and seeking to increase her medication dosage. She also reveals that she is struggling to cope with her eight-year-old son's problem behaviours, such as refusing to do homework and having tantrums when he fails to get his way. Using the dynamic maturational model of attachment, discuss how her mental health state could be influencing her child's behaviour.

❖ REVIEW QUESTIONS

1. Children generally double their birth weight by five months of age. This is an example of
 1. Development
 2. Heredity
 3. State of health
 4. Physical growth

2. _____ development is the ability of an individual to distinguish right from wrong and to develop ethical values on which to base his or her actions.
 1. Moral
 2. Cognitive
 3. Psychosocial
 4. Psychoanalytic
3. Theories in the _____ tradition hold that development is a result of biology and adaptation.
 1. Organicism
 2. Psychoanalytic and psychosocial
 3. Contextualism
 4. Dialecticism
4. Which of the following factors is considered an environmental factor that affects human development?
 1. Family
 2. Heredity
 3. State of health
 4. Genetics
5. The developmental theorist who believed his/her research described a sequential process that resolved conflict between the internal life (personality) of adults and their outer world (culture) was
 1. Erikson
 2. Crittenden
 3. Freud
 4. Havighurst
6. The zone of proximal development is
 1. The space between the individual's potential and his or her actual developmental status
 2. Where sensitive caregivers should operate to promote development of their young children
 3. A concept described by Vygotsky
 4. All of the above
7. According to Piaget's theory of cognitive development, during what stage does the individual's moral thinking move to abstract and theoretical subjects, such as achieving world peace, finding justice, and seeking meaning in life?
 1. Formal operations
 2. Concrete operations
 3. Sensorimotor
 4. Preoperational
8. The nurse who is working with a school committee to develop playground safety guidelines is focusing on which level of the bioecological model?
 1. Mesosystem
 2. Microsystem
 3. Exosystem
 4. Macrosystem
9. Which of the following nursing interventions is representative of a population health approach?
 1. Parent teaching
 2. Developing a clinical practice guideline
 3. Participating in a community coalition to improve community housing
 4. Assisting an individual in obtaining funding support for home care

10. A resilient individual is able to experience positive development despite challenging life circumstances. For a young single mother with two young children, access to high-quality day care represents the following:
 1. A vulnerability process
 2. A critical period
 3. Attachment
 4. A protective process

✦ RECOMMENDED WEB SITES

Canadian Institute of Child Health: <http://www.cich.ca>

The Canadian Institute of Child Health (CICH) is dedicated to improving the health of children and youth in Canada. Activities include research and policy recommendations and community development and resource building. CICH focuses on four key areas of activity: supporting healthy pregnancy and childbirth, fostering healthy child development, ensuring that the environment is safe for children, and monitoring the state of children's health.

Centre of Excellence for Early Childhood Development: <http://www.excellence-jeunesenfants.ca/home.asp?lang=EN>

The mandate of the Centre of Excellence for Early Childhood Development (CEECD) is to foster the dissemination of scientific knowledge about the social and emotional development of young children and about the policies and services that influence this development. The CEECD also formulates recommendations for the services needed to ensure optimum early childhood development. This page of the CEECD Web site lists a variety of issues and behaviours common to children younger than five years, with links to articles on the subjects written by leading researchers in the field.

Centre for Health Promotion (CHP): <http://www.phac-aspc.gc.ca/chhd-sdsh/index-eng.php>

The CHP uses a life stages approach and is responsible for implementing policies and programs that enhance the conditions conducive to healthy development. The CHP addresses the determinants of health and facilitates successful movement through the life stages. The CHP acts through programs addressing healthy child development, families, aging and lifestyles, public information, and education (Canadian Health Network), as well as on issues related to rural health and support of the voluntary sector.

Nursing Child Assessment Satellite Training (NCAST): <http://www.ncast.org/>

Based in the University of Washington, this organization aims to give professionals, parents, and other caregivers the knowledge and skills to provide nurturing environments for young children. NCAST disseminates and develops research-informed products and training programs for practitioners and researchers in many disciplines and settings, which can be used with typically developing children, with those at risk for developmental delays, and with those in whom special health care needs have been identified.

Review Question Answers

1. 4; 2. 1; 3. 1; 4. 1; 5. 4; 6. 4; 7. 1; 8. 2; 9. 3; 10. 4

Rationales for the Review Questions appear at the end of the book.

Conception Through Adolescence

Original chapter by Karen Balakas, RN, PhD, CNE
